	Linking theory to practice	Embed Multimedia and simulations, Use Students as mentors
3	Practising Discussion of ideas	Online debates, sharing etc.
	Rehearsing Skills	Interactive activities
	Practising Teamwork	Peer work and actual projects

EVALUATION OF THE COURSE COMPONENTS

Useful indicators of the effectiveness of the teaching are 'students' satisfaction about how the course was taught and what they believed they learned from it' and 'how a teacher assessed their own teaching' (Yates et al,1999) As promulgated by Yates et al (1999), a high standard of teaching is expected and the process of online teaching is more public and transparent than many anticipate. 'Expectations about what is quality service in providing education are different in a web environment' (Beckford and Fitzsimons, 2002).

The lecturer course portfolio proved to be a valuable resource in providing reflections on both successful and unsuccessful strategies. Comments from this have confirmed the findings of Lehtinen (1999) that the most successful strategies are those involving student collaboration, with timely and constructive feedback and encouragement from the lecturer. From the evaluation of this course and others, it appears that many of the qualities appreciated in face-to-face teaching are also those appreciated in online teaching. The strategy of varying the techniques in the exercises and tasks was instrumental in the success of this course. 'What has contributed to the success of the venture into online teaching has been the adaptations that teachers have made to their prevailing practice.' (Yates et al,1999) The adaptation of in-class exercises to online exercises in the course studied retained the hands-on approach. This required continual monitoring and the workload was not insignificant. However, care and attention to online questions and requests for help and guidance delivered their own rewards, that of effusive thanks from appreciative students. The porting to online of previously face-to-face class intensive lessons in interpersonal skills, and the total online and remotely controlled exercise of the training day have shown that with good monitoring, interaction and genuine interest in the students' progress, unlikely subjects for online teaching can be adapted successfully.

CONCLUSION

In order to improve delivery, documentation of the social, managerial and technological actions that instructors take are just as important as the pedagogical strategies used by online instructors. For this, the lecturer course portfolio or similar is ideal. Online teaching requires as much commitment to the students as face-to face teaching, albeit via a different medium. Appropriate interactivity is the key to success in online teaching. Students need to be allowed to discuss without intervention, unless help is needed. When help is needed, it should be timely and constructive, and this is why the instructors need to monitor the sites closely. Encouraging messages never go amiss. Lecturers always put their own flavour on any lesson, and experienced ones will devise innovative ways of using technology. But most important is the total commitment and interest of the instructor. The successful online instructors have 'built up a reputation for having staff that are enthusiastic about their teaching' (Yates et al,1999). As such, they will have provided variety in the course material and will have taught a useful variety of techniques. Online teaching requires interesting material and interested staff.

Creating Dialogic Enquiry in an Online Community

Jayne Klenner-Moore, PhD. (ABD)
King's College
Mass Communications & Media Technologies
Wilkes Barre, PA. USA

Abstract: This paper presents ongoing research into creating dialogic enquiry in an online community. There is evidence that the dialogic approach provides for better understanding of key concepts necessary for complex problem-solving in the traditional classroom (Wertsch, 1997). Does this hold true for online communities? Here the research is limited. Wells (personal correspondence, 2002) says that there is a definite potential for this area of research and that he has found that by providing what he calls "activity objects" into the online discourse students have more interesting debates. The problem of enhancing problem-solving skills, becomes increasingly important as we move more and more courses online, or add an online component to a traditional classroom (A blended environment). This paper will provide a model for implementing activity objects into a blended learning environment, and creating an environment that is conducive to dialogic enquiry, knowledge structure, and enhancing problem-solving skills.

Context

The purpose of this paper is to describe findings and observations from ongoing research done in a small liberal-arts college, criminal justice course, working with a blended learning environment. Dialogic enquiry includes a five-step model based on the work done at the inquiry home page site (http://www.inquiry.uiuc.edu/index.php3) (see fig 1.) and includes a combination of the problem-based learning cycle. Activity objects (Wells, 1995) are used to structure the dialogue and provide a goal-oriented activity to engage and promote the dialogue between students and instructor in an online community. This dialogue will mediate the knowledge structuring, which will then enhance problem-solving.

Jean-Paul Bronchart (in Wertsch, Del Rio, and Alvarez, 1995 p. 82) tells us that one of the meanings of mediation can be explained as "discourses formed have the status of open works – works on whose foundations subjects build their understanding of the world". This project was designed to help novice criminal justice students to understand the world of crime scene investigations. What do practitioners do in the field? The online community and dialogue helped students to develop questioning skills that helped build problem-solving skills germane to this field.

Meaningful action is formed by speech, and can be reflected upon by using textual representations such as those allowed for in message boards and chat rooms – features of an online community. "Discourses shape the educative action that is actually carried out within the framework of didactic systems" (Bronchart, 1995 p. 84). The question still remains how to design the activities in an online community that will be most productive in structuring students' knowledge about a subject so that they may become better at solving ill-structured problems. We based our activity objects around real crime scene photographs and allowed students to investigate on their own and with their peers, what those photographs represented. They then reflected on their discussions and were prompted to formulate analyses of these photographs to determine what had possibly transpired, to "solve" the crime.

A goal of this model is to develop optimal conditions for teaching in blended learning community where discourse is a primary ingredient in the blended environment teaching system. In this paper a model for achieving that goal, through the development of activity objects that can be used to spark the online discussion and aid in pushing the students through the enquiry cycle will be presented.

Sign, Symbol, & Language

Language is the medium through which we communicate ideas and come to know about the world around us. It is culturally mediated throughout the lifetime of the individual and meanings change through social interaction. Although, as Engström admits in his discussion of Russian theorist Bakhtin, and Wittgenstein's ideas of language, Activity Theory has only begun to properly integrate the idea of discourse. This model of dialogic enquiry is hoped to integrate Activity Theory and language as the main cultural tool to help students develop better problem-solving skills. In an online community language takes on the form of artifact, as it is now written and may be saved for later retrieval, as well as becoming a tool for reflection. Therefore, in our model for developing activity objects, there is requisite, a place for dialogue, both written text and oral dialogue which may take place in the traditional class as well as online. The forms of which dialogue help for reflection of the culture (Bruner, 1990), as well as reflection of the course content. It is this dialogue which shapes the learning and the construction of knowledge within the community of learners.

Practice

It is with the inclusion of the activity object, which provides for goal-oriented activity, that a community of practice, in this case an online community will stimulate the dialogue and promote knowledge structure. Engström and Miettinen give us the definition of practice as stated by Dewey:

> *It means that knowing is literally something which we do; that analysis is ultimately physical and active; that meanings in their logical quality are standpoints, attitudes, and methods of behaving toward facts, ant that active experimentation is essential to verifications.* (Deweyin Engström, Miettinen, Punamaki, 1999 p. 6).

Activity theory is concerned with practice as it is the outward exemplification of the outcome of the activity as well as the place where we can study the interaction of culture, division of labor, community, and rules among other things. Practice is one of the biggest areas currently under investigation among Activity Theory researchers.

Developing the Activity Objects

In 1996 King's College began to look more closely at building a "classroom without walls" (Mech conversations, Teagle Grant project). One of the ways that we started this march was through the addition of list serves to the classroom environment. We discovered much to our chagrin that students just didn't talk much online unless the teacher directed them to the discussion. We needed to find a way to "prime the pump, so that students would begin to use the technology to enhance the classroom experience.

What was needed for this course were activity objects that would stimulate the dialogue in the online community and allow for students to follow the inquiry cycle as noted in figure 1, below. The model that we employed brought together the traditional classroom and the online community to facilitate the enquiry cycle.

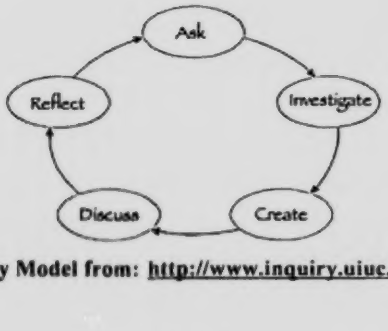

Figure 1 Enquiry Model from: http://www.inquiry.uiuc.edu/index.php3

BEST COPY AVAILABLE

In the classroom environment, students were introduced to course content and concepts for criminal investigations. They discussed various methods for interpreting what they saw in simulated crime scenes. In this course they became what is often referred to as a "community of practice", (Wenger, McDermott, Snyder 2002) also referred to as communities of learners or COLs (Jonassen, 1999). A community that shares a goal oriented environment. The practice that these students were involved in was the practice of crime scene analysis. The goal for students was to develop problem-solving skills related to this practice.

For the online community we used WebCT where students had the use of chat rooms for discussion, a form of instant messenger, as well as links to course content and the activity objects. Our activity objects were taken from real crime scenes and created on a web page. Students viewed the web page and then went into their assigned chat areas to discuss the photos. You may view the exam page, which includes the crime scene photos and the exam questions at http://www.kings.edu/jkmoore/cj/exam/. [1] Each activity object was developed following the same format as the exam questions. This allowed students to solve novel problems (Jonassen, class notes) using the same mental models that were constructed during the dialogic enquiry phase of the learning experience.

Students then followed the stages of the enquiry model. In this course we utilized a teacher-directed (Barell, 1998) discussion form. Other models will include student-directed, and student-teacher-directed (Barell, 1998) forms of dialogue.

In order to "solve" the problem that is presented by the question, students use the activity object as a tool to ask questions of each other. They begin by *asking* questions about the activity object (photo), then using class notes, other web sites, and the library try to *investigate* information that will help to answer the question. It is during this investigation stage that the students begin to take ownership of the learning process and to synthesize information that will carry them to the next stage (Inquiry Home Page, 2001). In the next stage, *create*; students now begin to formulate a solution using prior knowledge and creativity to come up with the new possibilities for a solution. Now that each student has some idea of what a possible solution may be, there ensues another dialogue where each student presents his ideas to the group, at this point the dialogue take the shape of a debate. And it is here that the social co-construction of knowledge begins within the community. Simultaneously, students are able to *reflect* on their own and others solutions. This then brings our cycle back to the "start" and more questions and dialogues begin.

It is important to note that this process will follow the cyclical routine not once but many times until the problem is solved by the students. In addition, each domain will require that the instructor who wishes to employ this system study the community of practice from which this domain springs.

Future Explorations

At King's College we will be continuing the work with two additional courses in the criminal justice department to test the validity of our instruments and the specific form of dialogic enquiry which will work best online. In addition we have enlisted the aid of several different departments to test this theory and model across domains. We will be developing activity objects for courses in accountancy, philosophy, theology, history and mass communications. It is our hope that a model for development can be made available to all departments on campus who utilize an online community in any form.

BUILDING THE LEARNING COMMUNITY THROUGH TEAMING AND TECHNOLOGY

Cheryl S. Knight, PhD., Director
Dianne B. Barber, Ed.S., Coordinator

Adult Basic Skills Professional Development
Appalachian State University
Boone, North Carolina 28608

ABSTRACT

The Adult Basic Skills Professional Development Project (ABSPD) is a collaborative effort between the North Carolina Community College System and Appalachian State University. ABSPD is committed to enhancing the quality of Basic Skills instruction in North Carolina through providing relevant, timely, accessible, and effective professional development for program faculty and volunteers, create a cadre of Certified Resource Specialists, and develop better instructional skills for the classroom in community colleges and community-based literacy organizations. ABSPD accomplishes this mission by using a team approach to produce multi-media train-the-trainer materials and workshops to build a successful learning community. The presentation will model the teaming approach used to produce training materials. Samples of project media will be featured.

INTRODUCTION

The Adult Basic Skills Professional Development Project (ABSPD) began in 1988 as a one-year project funded by the North Carolina Community College System. ABSPD is housed at Appalachian State University in the Department of Curriculum and Instruction. It is now in the 15th year of providing state-of-the-art professional development to enhance the quality of Basic Skills instruction in North Carolina through building the capacity of community colleges and community-based organizations to provide relevant, timely, accessible, and effective professional development.

ABSPD uses the team approach to produce multi-media train-the-trainer materials and workshops to build a successful learning community. This paper presents the teaming approach used to produce multimedia in a train-the-trainer program to enhance a collaborative teaching effort in the learning communities of community colleges, higher education, and literacy-based organizations.

THE TEAM

The ABSPD team consists of four full-time, one part-time and two graduate students team members housed at Appalachian State University. Each member plays an indispensable role in the planning and production of training media and events. The team meets twice a year with an Advisory Board and consults with the State Office Basic Skills staff on a regular basis. The team meets weekly to discuss progress and future goals.

THE TEAM APPROACH

The planning and production of training media and events is a team effort in which each member plays an indispensable role. From the brainstorming of ideas for content and layout to the final evaluation, each team member makes significant contributions. When the Advisory Board request a training product the team begins reading, generating ideas, and taking notes. The team members convene to share thoughts as they piece together the puzzle that will result in a quality media production. Next one team member takes primary responsibility for writing a script, outlining a plan, or putting structure to the project. Rough drafts are distributed to the team for editing, changing or rewriting. The team meets in a seminar to discuss the draft and add ideas for incorporating graphics, sound, video or other media enhancement to the product. The input is then incorporated into the writing of the next draft while team members, among their other responsibilities, video tape scenes, search for graphics, music, etc. After several meetings to present findings and refine the script, it is time to work on the artsy domain, the designing of storyboards and preparing mockups to provide a visualization of the training concepts. Again the team convenes to give feedback, each member contributing questions and answers from his or her own prospective.

Now is the time to begin the media product, but again the team effort is imperative. From experience, we have learned that waiting to view until the product is thought to be complete is a poor procedure. Too many changes must be made and often they seem to constitute a total makeover. The ABSPD team meets at least weekly to view progress, redesign, discuss changes, and reach consensus on acceptability. Often between meetings emails are circulated requesting feedback on a frame, a video clip, selection of graphics, or any other detail that impacts the quality of the media.

At last edits are complete. Time has come for the grand showing. The team gathers to view the culmination of our collaborative efforts, be it a video or the opening of an institute. As the event begins, we witness ideas come to life as the product unfolds on the screen capturing its audience through sight, sound and touch.

THE TRAINING

Multi-media productions include videos and CD ROMs. The training videos are accompanied by a manual and viewing guide. Annual institutes provide training in techniques of professional development, cutting edge research, integration of skills with a contemporary theme, and an infusion of technology. The ABSPD project plans and presents regional, individual community college and literacy organization workshops in which multimedia programs dominate. In addition, the ABSPD team publishes quarterly newsletters, maintains a current web page, presents at professional conferences, and consults with basic skills professionals throughout the United States.

During 2001-2002, training for professional development and other major activities consisted of the following:

- Developing technology support through video productions and web page accessibility;
- Writing Instructor Training Manuals;
- Producing a CD ROM;
- Providing assistance in planning and presenting professional development with community colleges, community-based organizations and Basic Skills programs;
- Designing the 2002 Summer Institute, "Focus on Cultural Awareness Through Writing."

The ABSPD team produced three videos emphasizing GED 2002: Writing and Reading, Social Studies and Science, and Mathematics and the Scientific Calculator, featuring information necessary to properly teach for successful completion of the GED 2002 Test. Each video begins with a history of the GED and information applicable across testing areas. Videos are designed for use both in individualized professional development and formal group training. They present complete information for preparing an instructor for teaching adults in GED programs. Integration of critical thinking in all skills and academic areas is emphasized. A printed viewing guide accompanies the videos to enable interaction and processing of content in both individual and group settings.

The project team published a three volume series, Adult Basic Skills GED Training Manual, coordinated with the video series. The manuals contain a narrative chapter, lesson plans, glossary and resources, all compiled in 3-ring binders for easy use.
Because instructors must apply generic skills and information across the curriculum, chapters entitled "Critical Thinking" and "Adult Characteristics" are included in all three manuals. For each content area the narrative and lesson section can be pulled out and used individually. The lesson sections contain suggested activities that teach content and skills. They are not intended to be inclusive, but do model integrated multi-level instruction, a model that must be implemented in our adult classrooms if students are to learn to think critically and make application both on the test and in life.

The ABSPD team wrote and produced a CD-ROM that focuses on using the scientific calculator. The first section introduces the calculator as a tool. The second section teaches the use of the calculator to perform basic and intermediate functions. The third section teaches the use of the calculator to perform advanced functions. Practice is provided for each key. The CD-ROM is designed to train instructors in using the calculator with Level I Basic Skills through Adult High School math students. Instructors can also adapt the CD-ROM for student use.

The team collaborates with the North Carolina Community College System office to provide assistance in planning and presenting professional development for community colleges. We consult with national projects, state programs, and community-based organizations. The team incorporates technology to provide training through a Certified Resource Specialist Retreat and numerous GED 2002 workshops. This year we presented formally and informally at conferences using multi-media, shared media products with other programs across the United States, and made ABSPD products available for purchase outside North Carolina.

The team collaborated to design the 2002 Summer Institute, "Focus on Cultural Awareness Through Writing" for 120 directors, instructors and literacy volunteers. Due to the North Carolina budget crisis, it was cancelled May 9, two weeks before the Institute was to begin.

The rapid shift of societal expectations for home, school, and community has placed a heavy focus on technological changes that allow faster and more efficient communication. As all of us become more dependent on technology as a communication tool, educators recognize the impact technology has on instructors and their students. Meeting the challenge of technology requires a respect of each team member's expertise.

The ABSPD web page is available on the Internet. It provides immediate information about the ABSPD project and Adult Basic Skills education across the state and country. New and updated information is continuously added to the site. For convenience and efficiency, it is linked with the North Carolina Community College Literacy Resource Center and other literacy locations.

The Impact

Impact on the community college Basic Skills programs and community-based organizations provided by the ABSPD Project as communicated by directors and participants includes the following:

- Provides participants with the competencies for conducting on-site training
- Provides quality training in areas of need
- Enriches instructors' knowledge of instruction
- Provides individualized training
- Mentors colleagues
- Organizes professional development opportunities
- Teaches trainers how to customize training
- Conducts training in new instructor orientation
- Prepares instructors for leadership roles
- Provides specific instruction on teaching the adult learner
- Motivates increased learning, informed teaching and collaboration
- Builds confidence in trainers and instructors

A survey, conducted annually, request respondent to rate the usability of the materials produced by the ABSPD team. The respondents rate the products as meeting their training needs. Several directors left blank the columns for advanced technology related training products indicating a need for greater support, referring to adequate hardware, software, and training, in using the web and CD-ROMs as training devices.

CONCLUSION:

Collaboration between ABSPD and the North Carolina Community College Adult Basic Skills staff provides multiple ideas and approaches that otherwise would have never been voiced. The synergy generated verifies that ideas added to ideas generate a sum greater than the parts.

Morph Chat: A Multimodal Instant Messaging System[1]

Abstract: The acceptance of Instant Messaging Systems (IMS) is increasing within the outreach education community with the growing popularity of distance learning. Instant Messaging Systems such as WebCT chat (2002) have become a part of distance learning in many schools in America. Morph Chat, a multimodal IMS, is the next generation of instant messaging. It is multimodal in the sense that it makes use of audio as well as visual communications to convey information to the users. The research described below, talks of a multimodal IMS, which uses animated agents (Johnson 2001) as the virtual representatives of users.

Introduction

Instant Messaging Systems (IMS) are the ideal means of communication for short and focused queries where an answer is needed quickly. With instant messaging the user knows before asking a question that the recipient is available to answer. IMS lead to instant feedback versus the traditional e-mail where, a question is asked and then answered possibly at a later time. The answer may result in another question. Getting to the final answer may take some time. With instant messaging, the user's question is answered in real time so s/he can quickly respond and get the final answer. This platform has proven to be crucial in distance learning environments such as WebCT chat. These IMS give the enrolled students a virtual presence out of the classroom. It is more interactive than video taped classes since it gives the outreach students a chance to interact not only with the professor but also with their classmates. However current IMS are text based and require constant user attention.

Traditional instant messaging has been deployed as a textual dialogue. Then came the computer-to-computer and computer-to-phone vocal conversations, where users were allowed to make calls from the computer to another user's computer/telephone and talk via computers. This system needed extra hardware, i.e. microphone. A close observation of the existing IMS show that none are multimodal interfaces.

Multimodal Interfaces

Traditional Web browsers visually render Web pages written in HTML, and user interaction is primarily done through the keyboard and a pointing device such as a mouse, roller ball, touch pad or stylus. In contrast, voice user interfaces, present information using a combination of synthetic speech and pre-recorded audio, and allow interaction using spoken commands or phrases. The input options are speech, keypads and pointing devices and electronic ink. The output options are speech and audio, plain text and visual displays. By using two or more of these input and output options a multimodal user interface is created.

Multimodal interfaces can be exploited a few different ways. A couple of them are:

- **Usage of more than one output mode to present complementary information**: In many cell phones, voicemail notification is done using a certain pre-set beep as well as a graphic showing an envelope opening or closing. This presents the same information using two different modes.
- **Choice of selection between different modes depending on the context**: Cell phone users are given two options to send a textual page. One is to type in the message using the keypad or call a call center and speak out the message, which will be typed in by a representative as text to be sent to a specific user(s). So users can switch between modes of input depending upon convenience and necessity.

Morph Chat — A multimodal interface

The two output modes used by Morph Chat to communicate information are visual and auditory. The visual output mode uses text messages and facial expressions. The auditory output mode uses synthetic voices through text -to-speech. Upon entry into the Morph Chat system, users will be prompted to select a random name to use as an identity for sending messages. When the user selects the name and enters the system, s/he is prompted to select a persona from a pop-up window. The user will see the controls of the chat outlet in the parent window are disabled. The user has to select a persona from the pop-up window to be able to send instant messages. As soon as the user clicks on an image representing a persona, this pop-up window is closed and the initially disabled controls in the parent window are made active. At this state the user can send and receive messages to/from the other users who are online.

As users log in, the persona representing them will come up to tell all the other users, that this person has logged in. At the same time a green box will be added to a set of similar boxes to announce the arrival of the new user, David (see figure 1). These boxes represent the chat names of the users and default to the color red.

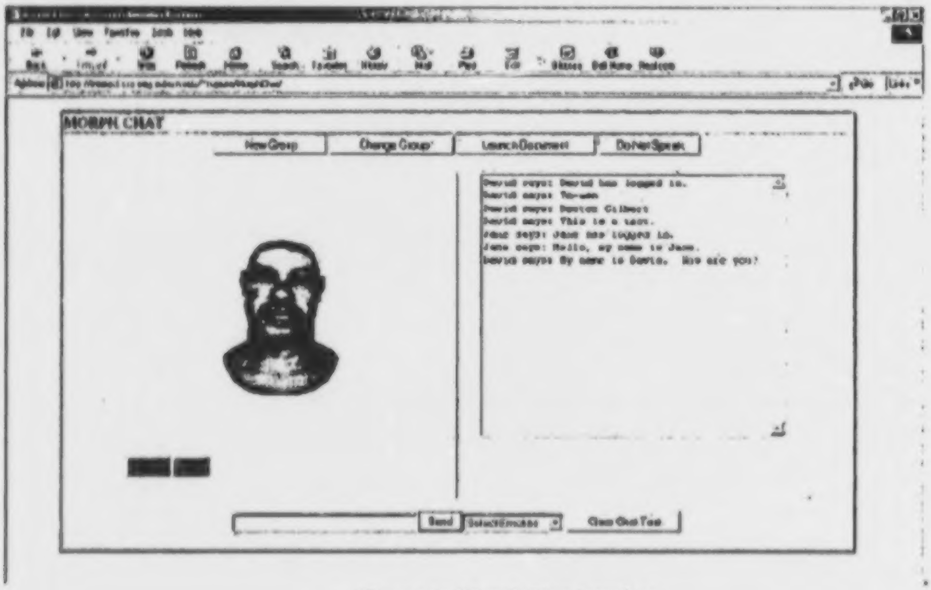

Figure 1: Morph Chat Interface

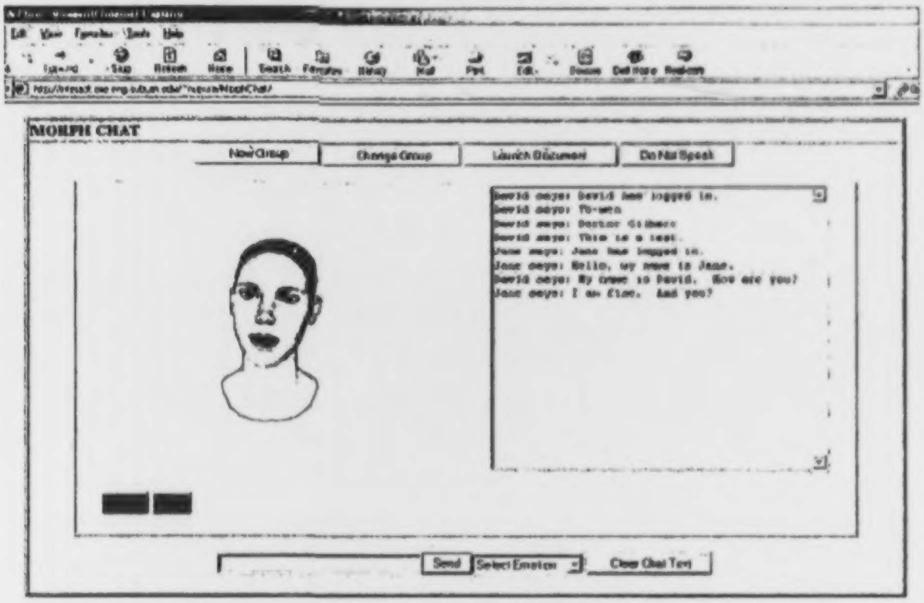
Users send messages by typing in text and pressing the Send button or the return key. When David sends a message, the persona that represents David appears on every users screen and speaks the typed message on everyone's screen. To use this application, users need not be pre-registered.

BEST COPY AVAILABLE

Figure 1 and Figure 2 show a conversation between two users David and Jane. David logs in first and then Jane. Jane's login is announced. Figure 2 shows Jane represented by the persona she selected. A green box with Jane's name on it indicates that Jane is talking at the moment.



David says: David has logged in.
David says: Yo-wen
David says: [illegible]
David says: This is a test.
Jane says: Jane has logged in.
Jane says: Hello, my name is Jane.
David says: My name is David. How are you?
Jane says: I am fine. And you?

Figure 2: Morph Chat Interface

The Morph Chat system does not require extra hardware for use. The users do need to download Haptek plug-in to be able to send instant messages. Haptek has provided a free version at http://www.haptek.com. If a user does not have this software, Morph Chat offers a download option from within the application window.

Morph Chat – The Architecture

On the server side of the Morph Chat application, a database stores all messages. Though the users are not expected to pre-register and provide personal information, the identity can be proven through the IP address of the workstation used. Hence it is very important that the users know that privacy is restricted. This application is completely time dependent. Each user's action is time stamped. Every message, emotion and/or document sent across from one user to all the other users becomes a row entry in the database. Each entry has a time stamp. The table is sorted in descending order with the latest time to be the last entry. Messages are selected based upon their time stamp every two seconds or when the client side message queue becomes empty.

At the client end, there are two local queues, which get data from the server: the user queue and the message queue. The user queue contains the data of all the user names of the users currently logged in. This queue is locally parsed into each individual name, which is then displayed as a green box on each user's screen. The message queue contains the user name, the persona ID, the message to be sent, emotions and the Web document address of a Web page to be launched on each user's machine. A variety of functions parse this queue in the order of the data received. First the persona representing the sender of the message is displayed, then the green box turns red, the persona speaks the message, expresses the emotion if any and last the message is displayed in the text area of the application. This process is recursive in its functioning until all the messages in the message queue are processed. When all of the messages are processed, the client's machine will go to the server to retrieve more messages. If there are no messages in the database queue, the client will check for messages every two seconds.

BEST COPY AVAILABLE

Conclusion

As Instant Messaging Systems (IMS) increase their presence in distance learning environments, Morph Chat will prove to be a crucial tool as a multimodal IMS application. Morph Chat will give users an opportunity to choose between the modes of communicating and thereby reduce the stress of constant user attention. Users can listen to the messages sent by an instructor in addition to reading the messages. The Morph Chat interface provides users with an interactive, animated instant messaging environment that proves to be entertaining as well as effective.

The important features and usability of the Morph Chat system will be clearly demonstrated during the presentation. The presentation will include a demonstration of the Morph Chat environment with multiple participants. The architecture and implementation will be discussed during the presentation as well.

A Unified Content Strategy for Learning Materials

Pamela Kostur

kostur@rockley.com

Abstract: A unified content strategy is a repeatable method of creating consistently structured content for reuse, managing that content in a definitive source, and assembling it to meet diverse needs. A unified content strategy applied to learning materials means that you can serve the needs of different learners and learning objectives, and potentially, deliver dynamic content adapted to learners' unique styles and objectives. You can also unify learning materials with other information products such as brochures, reference manuals, and user guides, so you write content once and use it wherever it is required.

What is a unified content strategy?

A unified content strategy is a repeatable method of creating consistent content for reuse, managing that content in a definitive source, and assembling it to meet diverse needs. A unified content strategy applied to learning materials means that you can serve the needs of different learners and learning objectives, providing learners with content adapted to their unique style and objectives. A unified content strategy also connects authors throughout the organization, allowing content from one area to be used in materials created in another area and reducing authors isolation, creating content that other authors may also be creating content for.

In a unified content strategy, all information requirements are identified up front (e.g., learning content, objectives, evaluation, instructor's guide, supplementary materials). Content is broken into "elements" or reusable learning objects (RLOs) that are stored in a single source or location, such as a database. Elements are identified by metadata describing such things as what objectives they satisfy, who the intended audience is, the information product in which they belong (e.g., student guide or instructor's guide) and the type of learning they support (e.g., receptive, guided discovery). Once elements are defined and described, they can be used wherever they are required. Elements can also be published dynamically to support learners' individual needs (such as experience, language, learning style) and to respond to how well they are doing as they progress through the materials.

A unified content strategy also means that learning materials can be "unified" with other information products such as brochures, reference manuals, and user guides. Elements that are used in the user and learning materials can be pulled from the database and reorganized into marketing materials such as brochures, press releases, and customer demonstrations. In this way, wherever the same content is used, it is consistent. For example, while analyzing one organization's materials in an attempt to unify content across nine different courses, we found four different definitions of the same term, in all nine courses. In another case, we discovered a course description in a brochure that differed significantly from the course description provided in the actual course. These kinds of inconsistencies can result in confusion (caused by students learning incorrect information), they can damage your organization's reputation, and they can also result in accidents and law suits.

Benefits of a Unified Content Strategy

A unified content strategy is a coherent content strategy. Organizations can rely on content being the same wherever it appears, providing both internal and external customers with a consistent message, brand, and accuracy. No longer do organizations have to worry about contradicting themselves with differing information; where duplication occurs, it is the same content. Additional benefits include faster time to market, better use of resources, reduced costs, and improved quality of content.

Faster time to market is achieved through shorter content creation and maintenance cycles. Authors spend less time repeatedly authoring content because they reuse existing content wherever possible, supplementing it where appropriate. For example, the steps that appear in a product user guide can become the same steps in the training materials, supplemented with objectives, examples, and exercises. Reviewers also spend less time reviewing content because they only have to review the content that is new or changed; content that has already been reviewed

BEST COPY AVAILABLE

and signed off doesn't need to be reviewed again. In the case of reusing steps from user guide to training materials, reviewers would only have to review the steps once instead of in two different places—after all, they're the same steps.

In a unified content strategy, you make better use of your resources because the repetitive processes of creation and maintenance are reduced. Because they are required to do less repetitive work, everyone involved in the content creation process can do more value-added work or respond to new requirements. For example, instead of cutting and pasting materials from one document into another one (e.g., from student workbook to instructor's guide), authors create the reusable element once and use it wherever it is required. When they have to update the reusable element, authors don't have to search for all the places it appears. Instead, the element is updated automatically (or, depending on the technology to support your unified content strategy, authors are notified when an element they have reused is updated). Because the often tedious work of cutting, pasting, and tracking content is reduced, authors can spend their time on what they do best—supporting learners with good learning materials.

Because repetitive tasks are eliminated, the costs of creating and managing content are also reduced. Less work is required to get a product to market, not only decreasing internal costs, but potentially increasing revenue. Content is modified or corrected once instead of multiple times, reducing maintenance costs. Translation costs are also reduced because reusable content is translated only once instead of multiple times.

A unified content strategy even helps to improve the quality of content. Content is clearly modeled for consistent structure; increasing its readability and usability. Most importantly, content is accurate and consistent wherever it appears. Issues of inaccurate content, inconsistent content, or missing content are reduced or eliminated.

A unified content strategy also supports SCORM (Sharable Content Object Reference Model), an initiative of the ADL (Advanced Distributed Learning Network) whose primary goal is to provide high quality instruction anytime, anywhere, tailored to individual learners' needs. SCORM accomplishes this by modeling information for different uses and ensuring individual components comply with certain standards for reuse. The SCORM standard is an XML-based industry formalization of the concept of single sourcing. It is similar to the information modeling approach we follow in our unified content methodology.

Applying a unified content strategy to learning materials

To apply a unified content strategy to learning materials, you need to figure what content your learning materials consist of, determine everywhere that content is used and can potentially be reused (within one course, across courses, as well as across other information products), then build a model that supports sound instructional techniques as well as content reuse.

The pedagogical model

Effective instructional design includes three components: prepare (read/view material), do (perform learning activities), and reflect (consider what was learned; apply skills). To develop a pedagogical model that supports these components, you need to:

- Define information types and the learning architectures appropriate for the materials
- Define and incorporate interactivity
- Design learning activities
- Create a course structure that guides learners through the materials, allowing them to work through the materials in a manner best suited to their needs and the type of information they are learning

The unified content component of the pedagogical model requires that you go beyond building a solid course structure. Added to that structure is metadata, indicating in which course or courses each RLO belongs, as well as what type of learning it supports and which learning activities will be used to support it.

Types of information and learning architectures

Information type refers to the content's purpose. Two primary types of information are:

- Near-transfer – methodical, done the same way each time, such as a calculation
- Far-transfer – analytical, done differently depending on situation; similar concepts applied to different situations

Learning architecture refers to the way in which instruction is designed, at a macro level. The learning architecture describes the overall approach to the materials. The four learning architectures are:

- Receptive

- Behavioral
- Guided discovery
- Exploratory

In a unified content model, you tag elements as receptive, behavioral, guided discovery, or exploratory materials and delivering them to support the types of information and learners they are best suited for. In a receptive architecture, learners absorb knowledge and skills from listening to a lecture, watching a video, or reading text. Learners take information in, but there is no externally prompted interaction. Information is presented in text sequences, examples, analogies, visuals, etc. Receptive learning can cause cognitive overload (especially in learners with poor metacognitive skills) if other learning strategies aren't incorporated with it. It's good for building up a good source of information, but—especially for novice learners—it must be balanced with other approaches to ensure the information is absorbed into LTM (long term memory).

The behavioral architecture assumes that learning occurs by a gradual building of skills and information, strengthened by interactions imbedded into the instruction. Learners are provided with small chunks of instruction (basic to complex), followed by an interactive session after each chunk. This approach is widely used in computer-based learning. It manages cognitive load and encourages encoding of information into LTM through frequent interactions. It works very well for teaching procedural (near-transfer) information. However, it's sometimes tiring for learners with more experience. Also, by providing metacognitive regulation, learners don't get an opportunity to build their own metacognitive skills.

Guided discovery emphasizes the building of unique knowledge through case-based learning. Guided discovery is a more "constructivist" approach to learning; the instructional materials provide learners with the resources and experiences required to construct new knowledge. The emphasis is on construction instead of acquisition (which is the basis of the behavioral architecture). Learners are provided with a realistic problem or scenario, and access an array of resources to solve the problem. Guided discovery works well for far-transfer information, but it demands that learners have good metacognitive skills. However, it also helps learners to develop their metacognitive skills and to transfer their knowledge to the "real world".

Exploratory learning accommodates higher learner control. The assumption is that learners (especially in an internet environment) will access the information that best suits their needs. Depending on the amount of information to explore, overload can result, but keeping topics brief and adding frequent, optional practice, can help to manage the cognitive load. Exploratory architecture works well for both near- and far-transfer information, with other strategies employed within the architecture. However, the danger is that learners get lost while exploring. It also assumes that learners have the metacognitive abilities required to make the right learning choices.

There is rarely pure implementation of a single architecture. A combination of architectures is usually required to accommodate varying abilities, balance cognitive load, encourage learners to develop their own metacognitive skills, and teach different types of information (near- and far-transfer). With a unified content strategy, you can outline a number of different learning activities to support various learning architectures, types of information, as well as learner preference.

The unified content model

A unified content model should indicate how architectures will be combined, using metadata to indicate not only which course a learning object belongs in (as well as which other information products it can be used in, either identically or derivatively), but also, what type of learning (and learners) it supports and what learning activities will be used to support it. For example, in a recent project, we were tasked with building a model to accommodate nine different courses that were being moved online. During our initial analysis of the paper-based materials, we discovered much repeated material within courses and across courses. Sometimes, the repeated versions of content were inconsistent from course to course, and even within a course. In fact, learners often complained about the repetition and the inconsistencies. We determined that by reusing elements, we could reuse approximately 35% of the content and potentially, eliminate unnecessary repetition, making the courses more consistent and easier to work through.

The unified content model we developed for this project tells authors how each course should be constructed (hierarchically, based on the pedagogical model and type of information), what an element is (e.g., topic heading, learning content, learning activity, objective, knowledge check question), all the places where that element belongs, and which supplementary information should accompany it. Accordingly, the model includes metadata that describes in which course an element belongs (output) as well as additional descriptors, such as how well learners must "master" an element. (Metadata is simply information about information; in a unified content strategy, it allows authors to provide additional information about how an element is used and to track it.)

The metadata representing "output" tells authors (and the database in which elements are stored) where to publish a particular element. When developing storyboards for learning materials in which content is reused, we include a field for the metadata; authors simply enter the metatags representing the courses in which an element belongs. Metadata to identify output is critical in unifying content beyond learning materials. The same content can appear in a number of different places (e.g., the instructor's guide, the brochure) with more or less detail. Metadata defines everywhere that content will be used.

Additional metadata may not affect output (i.e., where an element is published), but it can be used to provide further information about each element. For example, some elements have to be learned at a particular "mastery" level. While the mastery level does not affect the output, it's essential to identify so that authors can tie evaluation directly to mastery level. There may be three mastery levels, all of which appear in one course. To pass the course, learners may have to acquire general knowledge of one topic (mastery level 1), but must have more applied knowledge of another topic (mastery level 3). Both topics, however, appear in one course. The element that requires mastery level 1 must be taught and evaluated at level 1; the element that requires mastery level 3 must be taught and evaluated at mastery level 3. By identifying mastery level as metadata, authors can easily identify what type of evaluation and learning activities to provide for each element. Further, if mastery levels must change, authors can quickly find all elements tagged with a particular mastery level and update them accordingly. Additional metadata may include such things as:

- Type of information
- Type of learning activity
- Learning architecture it supports
- Date
- Author
- Status
- Version

The unified content process—a summary

Implementing a unified content strategy involves:

- "deconstructing" all content from all courses into elements or RLOs
- assigning elements into outputs, based on learning objectives
- developing standards for and rewriting elements so they follow a consistent structure (consistency is critical in a unified content strategy) and conform to your instructional model that defines which learning architectures best support your content, objectives, and learners' needs
- compiling courses (and other information products) from their required elements, providing supplemental information as required to accommodate different learners, different mastery levels, and even different information products.

A unified content strategy requires much up front analysis; you need to break content down to determine how and where it can be reused and determine how best to write it to support its various uses and users. However, once the analysis is complete, courses can be easily constructed and kept up to date. Also, wherever an element is used it is consistent, eliminating unnecessary repetition.

Abstract: Transclusions were first mentioned in the early 1960 by Ted Nelson. Generally speaking transclusions are a method of reusing parts of a document without duplicating these parts. In the proposed implementation authors of documents will be informed (on request) if parts of these documents are reused elsewhere. Authors using transclusions are informed about changes in the reused document. Reused document fragments are marked in both documents to help readers while exploring documents. The concept is old but implementations are still not available to authors and readers. After a short introduction this paper shows some applications of transclusions. Thereafter ideas on how to implement transclusions using a second generation hypermedia information system are presented.

Introduction and Problems

The idea of transclusions was born in 1960, when Ted Nelson invented Xanadu, a revolutionary information- and document management system. "Reuse without duplicating document fragments with the original context available" ([Nelson, 1995]) is the key issue of the transclusion concept. Newly assembled documents are also called *compound documents*, on the other hand, documents reused in one or more compound documents are called *transcluded documents*.

As there is no duplication of document fragments when reusing content many advantages over ordinary cut-and-pasting of data arise (see e.g. [Krottmaier and Maurer, 2001]). In the following we are going to to numerate some of the advantages.

Intellectual Property: Parts of a document are not 'stolen' but simply 'reused in another context'. It must be visible to the reader of a document that parts of the document are no original contributions, but references or inclusions of some other work. Dependent on the electronic format of the compound document this is easily implemented by adding hyperlinks to the original work before and after the inclusion of the reused material. Please note that in HTML documents it is possible to reuse whole images in any context stored on any server system. The reader of the document will not notice this fact without reading the source-code of the HTML document.

Disk Space: Since parts of a document are not copied into a new document there is no need to save the reused part more than once. Surrogates of the reused parts must be stored in a predefined format. There will be no waste of disk space, if the surrogate definition requires less disk space than the referenced part. It is obvious that transcluded documents must be available to the system when assembling the document. Without coping the reused part and without sophisticated caching mechanisms this fact may limit the applications of transclusions to intranet or even intra-server applications.

Update: There is simply no need of manually updating referenced parts because the content is always requested from the *original source*. Since this is an advantage in many applications (e.g. a collection of different course material which is automatically up-to-date) there are drawbacks in some other applications where many people are responsible for the content and access control is not an issue. Some action must be taken if reused parts are changed. At least the author of the compound document must be informed (e.g. via email) by the system if there are any changes in the reused part. While there is no need to update a document it might be a time-intensive task to assemble a compound document. Therefore reusing a document which reuses parts of another document (which itself reuses parts of other documents etc.) must be limited to a certain level. Nevertheless, improvements in network infrastructure and processing speed will reduce this problem.

Two Way Reading: When displaying the transcluded document the system must add additional navigation facilities around the quotes in the compound document. This action is necessary to indicate the reuse of content (see 'Intellectual Property'). Links to the original source of the transclusion are provided. This makes it possible for the reader of a document to take a look at the original context of a quote. The reader of the transcluded document on the other hand has the ability to explore which parts of a document are no original contributions. If a fragment of a document is reused it is very likely that this fragment is important!

These are some of the most important advantages and drawbacks when using transclusions. Authors of compound documents must be aware of the risks when using this technology. The information system where these documents are stored must support authors in many ways (i.e. creation of transclusions, notification of changes, types of changes [Francisco-Revilla et al., 2001], etc.).

Applications of Transclusions

With the knowledge of the concept many existing applications can be improved. This section lists three possible applications. Please note that many other applications will profit from the idea of transclusions.

Electronic Publishing: Scholar papers often quote paragraphs or sentences of other already published papers. When using transclusions readers of the new paper are able to jump directly to the context of the quote (i.e. to the original paper). It is therefore possible for the reader of the compound document to explore the reused quote in the original context. This issue is especially useful for novices in a topic. The author of the compound document may create a special 'view' of a topic. Readers who are interested in the details may read also the original contributions to the topic. Readers of the transcluded document on the other hand are able to see which parts of a document are reused in other documents. This is a very important information! If a part of a document is reused in some other document, it is very likely that this part is very important. This additional 'meta-data' ("This part is also used in some other document(s)...") is a kind of implicit rating of a fragment of a document. In addition to attributes in link-objects (whether the part is used as a positive or negative example) useful information is added to the transcluded document!

Discussion Forum: In electronic written communication (especially in electronic discussion forums like bulletin boards or news groups etc.) many new postings refer to previous postings. These postings are (usually) immutable. In electronic journals or libraries this kind of communication is also very common (e.g. 'letters to the editor' often refer to parts of previous published articles). Referring to parts of an article should be possible by simply mark the fragment to be included in the new document or posting. Readers of the new article can be sure that the referenced part is not modified by the author of the new article. Also readers of the 'old' (i.e. transcluded) document are able to see which parts are discussed later in some other posting. On the other hand it is very likely, if the system is used in the right way and uses are used to it, that questions will be asked not more than once. A much more efficient communication will be the result when using transclusions in this kind of application. Time will also be saved because of additional structure in discussion threads.

Course Material: Very often existing course material is simply a collection of (unidirectional) links to related material stored on different server systems. Unfortunately it is not possible with current web technology to link to parts of existing material and to create links back to the collection. A very simple example will clarify this situation: imagine a single very important paragraph in an article of 100 pages. The author of the course material may add a link exactly to the paragraph, but can't include a link in the (remote stored) material *back to* the collection! Therefore the author of the collection has to cut-and-paste paragraphs of existing material into new documents. The original contexts of these paragraphs are lost.

BEST COPY AVAILABLE

These three applications showed the need for transclusions. Systems supporting transclusions will have a great impact in may areas. Proper use of transclusions and interoperability between these systems may help authors and readers of content stored on the web.

Requirements and Implementation

In scientific publishing the usage of quotes and references are very common. Readers of those publications have to do a lot of work if they want to explore a reference and want to find the original context of a quote used in another document. Systems like ResearchIndex ([NEC Research Institute, 2002]) are able to answer questions like "Where (i.e. on which page) is this reference used?" but it is not possible to explore the original context of the reused quote! Therefore we are motivated to implement this feature in the Journal of Universal Computer Science ([J.UCS, 2002]). In the publishing system used for serving J.UCS content is offered in several electronic formats to the readers. At the time of writing these formats are HTML, PostScript and also PDF. We consider the implementation of XML formated documents and also eBook-formated content.

In a first implementation we are going to support HTML documents (for both, source and destination document format) with additional hyperlinking information. The source and destination document(s) will be stored in a Hyperwave Information Server (HIS, see e.g. [Hyperwave, 2001] or [Maurer, 1996]), where it is possible to add link objects *without* being the owner of a document. Please note that inserting hyperlinks to HTML documents implies editing of the document itself. Note also that a link in HTML is unidirectional! A successor of the implementation will also consider other document formats (like PDF) and other source systems (like ordinary HTTP-server systems). Let us now sketch ideas related to the involved participants and systems:

Author of the original document: If parts of the document are reused in other documents this participant may want to be notified by the system. If the author wants to change a transcluded part of the document, the related parts should be marked. Note that in the original design of Xanadu (see e.g. [Nelson, 1995]), a "write once – read many" system was considered. Therefore it was prohibited to remove documents. Editing of documents was allowed *only* if the old version was still available and accessible by the system.

Author of a document using transclusions: It must be easy for the author who is using transclusions to determine the fragment of a document to be transcluded. Therefore easy to use tools must be implemented supporting the user in the creation of a new document. In a first implementation a simple JavaScript-based implementation will be used. While there are many drawbacks of this approach the user must not install a separate software and a prototype implementation will be available very soon. The selected part will be represented by links following the XPointer-specification (e.g. [DeRose et al., 2001b], [DeRose et al., 2001a]), therefore the selected fragment may be defined in many ways (e.g. use the 5'th paragraph, or use the first paragraph after the 3rd heading etc.). The links will be stored using objects on the server system.

System, where the transcluded document is stored: The system must be able to serve parts of a document. If documents are mutable, a version control system must be integrated to make old versions of the document accessible. Additionally, the system must provide the reader of the document (depending on personal preferences) with navigation facilities which indicates transcluded parts. If the author of a transcluded document edit some part of the document, the system is responsible for informing other authors using parts of the document about the change. Please note that bidirectional links are an absolutely necessary requirement for the system to perform this task. In the first implementation we consider a HIS as server system because of the many advantages over ordinary web-systems without link management and bidirectional link concept.

System, where compound documents are stored: This system is responsible for assembling the compound document. Navigation facilities must be included by the system to support the reader of the document. If the transcluded part has changed also the reader may be informed about this change. The author of the document has to define whether the user should be informed or not. In our first implementation also this server system will be a HIS.

Reader of assembled documents: It must be easy for the user to notice the reused parts of a document and to jump immediately to the original context of the reused parts.

Since there are many issues to consider, the first implementation will be very limited in terms of supported document formats and server systems. Nevertheless, future extensions are considered in the design of the software.

Conclusion and Future Work

This paper has shown that transclusions have many advantages for the web community and that there is a need for an easy to use system. Readers of a compound document have the possibility to *explore the original context* of the used quote. Authors of compound documents are able to easily *reuse existing material* and do not have to update reused document fragments. Finally, authors of transcluded documents knows *which parts are used* by other authors due to the bidirectional behavior of the used link mechanism. Transclusions have many advantages over conventional cut-and-paste reuse of content.

Future work is addressed to a first implementation in the Journal of Universal Computer Science. Thereafter usability tests and user responses will be evaluated. After successful tests authors of the journal will be able to use transclusions of articles published in J.UCS.

Abstract: At the moment it is not very common to actively work with material stored on an Internet server system. Once the right information resource is found, only passive information consumption of documents is provided by a majority of information systems. While this is appropriate for a kind of reading material, this is a limitation for scientific articles. Scientific articles are often read more than once, are usually annotated while they are explored, and are often the root of further investigations. In this paper we explore two features which will be available in the Journal of Universal Computer Science (J.UCS). These features will support the reader in exploring articles and will make it much easier to turn information into knowledge.

Introduction

Digital libraries are often the source of information. Three common steps are necessary to turn information into knowledge:

1. Find the right information.
2. Explore this information.
3. Apply the information.

Several tools are available to support scientists in finding the right information: search engines (such as Google) and directory services (such as Opendirectory) are often used as 'entry to the web'. While search engines are often used by users *who know exactly what they are searching for* and directory services are used by users *who do not know exactly what they are looking for*, there are also some system specific notification mechanisms available, which 'directs' users to sources of information. In the context of digital library systems this kind of service is called 'Alert Service'. These tools are currently well known and heavily used in the Internet community.

A few highly sophisticated features (such as 'find similar information resources') are already integrated in search engines and are inherently available in directory services . Other specialized application specific features are available in the server systems providing the information. In this paper we are going to discuss two features: an annotation feature and a personalization feature. We illustrate implementation details of these features. Annotations are available in J.UCS ([J.UCS, 2002]) since the beginning (1994). The personalization feature is currently under development and will be released in the near future. In J.UCS we use a Hyperwave Information Server (HIS, [Hyperwave, 2001]) to make the implementation of these features as easy as possible. In the following sections we explore some aspects of these features.

Annotations

It is very common to write handwritten annotations on paper or mark some regions of text as important or unimportant for understanding, especially in personally owned material ([Marshall, 1997]). "Dog-eared" books *are highly customized books* and the turned-down corner may be of great value to the "creator" while trying to find an interesting part of the book again! No matter what type of content (text or graphic) on whatever position may be annotated in a traditional library environment. It is obvious that it should be possible to annotate also material stored in a digital library environment.

Unfortunately not all digital library systems support the reader in the creation of electronic annotations although electronic annotations are much more powerful than "analog" annotations in a traditional environment. The following list illustrates features of electronic annotations:

Private Annotations: if the digital library system provides the user with an identification facility, it is very easy to support private annotations. Private annotations must be visible only to the author of the annotation.

Shared Annotations: if annotations are stored in an intermediate- or server system, it is possible that users share annotations. Therefore many users may explore the content by using annotations very quickly. There are many applications of this kind, especially if users are working in groups and/or are exploring online-available literature.

Typed Annotations: types like 'Question', 'Answer', 'Problem', 'Solution', 'Rating' etc. are needful in selecting whether to read or not to read the annotation or even the content. Additional attributes like 'User who wrote the annotation' may be very helpful.

Rated Content: A document may be rated by special annotations. Users may decide to read just articles with top ratings and may not waste their time in reading (obviously) poor written articles. Actual content (i.e. recently published content) must be treated in a special manner.

Nevertheless, some technical problems have to be solved and tools must be created to support users in writing and managing annotations. Let us now discuss some approaches and problems in conjunction with the annotation feature. There are different possibilities of the storage location of the annotations. Annotations may be stored on 1.) client-side systems, 2.) intermediate systems and 3.) server-side systems ([Krottmaier, 2001]).

Annotations in J.UCS are stored on the server-side, therefore they are easily accessible to all users or to a group of users. Annotations in J.UCS are 1.) indexed and therefore search able, 2.) interlinked via special link-types with the content and 3.) physically separated from the content.

We mentioned the term *information source*. This kind of source is a collection of documents which all represents the same content. I.e. if content is available to users in different formats (e.g. in PDF, PostScript and HTML) we talk about *one* information source but different formats of the content.

This fact introduces another problem: Annotations to the HTML-representation of the content should also be presented to users when looking at the PDF-version of the content and vice versa. On the other hand, not every reader of the PDF-version is able to create annotations because the annotation feature is not available in Acrobat Reader. The Adobe Acrobat API-license prohibits development of plug-ins supporting annotations. Therefore another solution without using the PDF-inherent annotation facility must be developed. Currently we explore two approaches to solve this problem: feedback forms for *each page* in the document and hyperlinks from *each section* to an annotation server application.

There are many applications of annotations. One application is the '*active documents*' concept ([Heinrich and Maurer, 2000]). Active documents introduce a system which may automatically answers questions. Users may ask any question at any position in a document stored on the server system. The system either answers the question automatically (by searching for answers to similar questions), or forwards the question to the author or maintainer of the document. If there are many users of the library and if the tools are easy to use, there is an enormous power in using this idea of active documents! But also other applications are possible: e.g. an *intelligent automatic summary* of a document. This summary can be as easy to implement as collecting and displaying all highlighted document fragments which are created by the readers of the document. Again, many users may increase the quality of these summaries.

There are many studies about how annotations are written in an electronic environment (e.g. [Marshall et al., 2001]). Many web based based environments (e.g. [Rosenstock and Gertz, 2001], [Kahan et al., 2001]) are using annotations. Annotations are a necessary feature in every system providing information to a large community.

Rearrange Documents and Document Fragments

Organizing whole content entities or parts of content in a user defined way is essential when improving the usability of digital libraries ([Krottmaier, 2001]). We are currently implementing such a *server side personal data collection* in the environment of the Journal of Universal Computer Science. This makes it easier for readers *to work with the content* of the library. In the upcoming prototype it will be possible to simply select information sources (in our case articles and article collection) stored on the server and link them to a personal collection. As a result of the integrated link database, the collections will remain up-to-date even if objects are moved to some other location on the server. Therefore the infamous `'HTTP-error 404'` ('Page not found') cannot appear when accessing objects stored in the database.

Such a personalized data collection may be static or dynamic. The example above showed a static collection, where each article must be selected and linked to the collection. If there is the request to visualize 'all articles by author XXX' or 'all articles in category YYY', this approach is not very effective. Therefore other possibilities must exist: to answer the first question (articles by author), so called *query objects*, i.e. objects, representing a search query in the database, will be used. When these queries are executed, all matching objects will appear in the listing of the personal collection. The second question (articles by category) can be answered by linking the appropriate category-collection organized by the administrator to the personal collection of the user.

Since we are using an object-oriented database system (Hyperwave Information Server, HIS) which supports inherently users and groups, it is possible to implement *public* and *private* collections of articles simply by assigning the proper 'rights'-attribute. Public collections may be used as a kind of *public bookmarks* already implemented by a lot of services (e.g. [MyBookmarks, 2001]). But there are several other advantages, including accessibility, when saving bookmarks on the server-side rather than on the local file system in some browser-specific format.

Organizing objects stored *on* the server system (*local objects*) is obviously not sufficient in the context of an open digital library system. It must also be possible to organize objects stored on any other system (*remote object*) like HTTP-server systems, other internet based systems, and even files stored on the local file system.

To enable structuring of remote objects a surrogate object must be created in the database. This object (in Hyperwave terminology also known as 'remote object') is then used as handle for further operations. Since the control of the referenced part is completely up to the remote server administrator, tools (such as link checkers and content watchers etc.) must be integrated to support the user while working with remote objects.

Structuring a single document as one unit is easy compared to the task of structuring parts of a document. Resources are usually addressed by URLs (Uniform Resource Locators, [Berners-Lee et al., 1994]). Depending on the document format, more granularity is possible.

We should not limit this discussion of fragments of a text based document (such as HTML, XML and PDF). A user may address the upper left part of an image, or the first 5 seconds of a video, etc. There is much work to do, to implement this feature.

Conclusion and Future Work

In this paper two necessary features were described in the context of the Journal of Universal Computer Science. Problems and issues of the well known annotation feature were presented and ideas on how to personalize documents and document collections were discussed.

In the current implementation it is not possible to add annotations *at any position* in the HTML representation of the information resource. Only whole content objects may be annotated at the time of writing. Although this approach is suitable for small documents, it is inappropriate when working with large documents. Therefore future work is addressed to make it possible to addannotations to parts of documents – simply by selecting a corresponding document fragment. Sharing annotations between different document formats is also an issue in the prototype.

The current working prototype does support rearrangement of locally stored objects, but does not support restructuring of document fragments. The next step is therefore to organize and restructure parts of documents.

Abstract: EDUCO is a system for collaborative learning that uses real-time direct social navigation. Social navigation means making the navigation of other users visible to everyone else in the system. The paper discusses the social navigation features of EDUCO and reports empirical results regarding the collaborative behaviour of the students in a university-level Web-course. Contrary to our research hypothesis and the common wisdom in the research area, the data gathered showed that making other users' navigation visible did not have an effect on navigation in this experiment.

Introduction

Social navigation (Munro, Höök and Benyon 1999) provides interesting opportunities in collaborative e-learning. When simplified, social navigation means that the users of an environment are dynamically provided with the information of the actions of other users of the same environment. A trivial example is a counter on a Web page, showing how many other people have visited the page. In their seminal book about social navigation, Munro et al. (1999) use an on-line grocery store as an example when classifying different types of social navigation: if people visiting the store are given recommendations what other people have bought, it is a form of *indirect social navigation*. If a shopper in the grocery store has a sense of other people moving about the store and can engage in seeking e.g. assistance, it is a case of *direct social navigation*.

Experiments with social navigation in educational setting have mostly fallen into the category of indirect social navigation (see e.g. Dieberger 1999). However, EDUCO is a system for collaborative learning to employ real-time direct social navigation. Real-time aspects of EDUCO create the feeling of live companions in the system (Kurhila et al. 2002). Other important facilities include tools for synchronous and asynchronous communication, and support for forming study groups and publishing their work. The purpose of the paper is to demonstrate how the tool was applied to a real-life situation, and describe how the features of social navigation are empirically evaluated from a data gathered from a university-level course of 46 students.

System Description of EDUCO

EDUCO is a system for both the learners and the teachers, to be used with standard web-browsers. From a technological point-of-view, EDUCO consists of a socket server along with cgi-scripts, and a Java applet for every user. From the user point-of-view, the key issues are navigation towards useful information, synchronous and asynchronous communication, group forming and publishing group works.

There is no direct metaphor for the use of EDUCO in traditional classrooms. A learning area in EDUCO consists of the EDUCO tool itself, a view to a document, and comments for the document. The user interface of EDUCO tool consists of different views of which only one is visible at a time. The most important views are map, chat, search and alarm (Fig. 1).

Jaakko: Do you have room in your group?
Miikka: Sure, what kind of an angle you have been thinking?

first, lets write about course

Title: Overview of Web-Ba
URL: http://www.outreach.

Person: Miikka Miettinen
Group: 3
Documents: Free

Notify when Miikka Miettinen or somebody from group 3 enters the system.

Figure 1: From left to right, four different views of EDUCO: Map, Chat, Search and Alarm.

Map view presents documents currently available in the learning environment and provides a way to navigate to them directly. By double clicking a document a user can open it in the rightmost frame in the browser window. A user is represented as a coloured dot around the document he or she is currently viewing (Fig. 1). Other users are visible to every user in real-time, so that their navigation is visible to everyone present.

The documents change their brightness level and colour on the map depending on how much they have been viewed relative to the other documents, as seen in Fig. 1. The total time all users have spent viewing each document is recorded every hour. The change in the brightness and in the colour of an individual document are determined by the distance of its moving average for the last 24 hours from the same average for all documents.

In other words, map view provides the users of EDUCO two social navigation features. Colouring the documents according to how much they have been viewed is a form of indirect social navigation. Presenting users as moving dots next to the documents they are currently viewing is a form of direct social navigation. Both of these features can help the users to follow the footsteps of the others. The direct social navigation also adds to the sense of not being alone in a web-course (Kurhila et al. 2002).

EDUCO has a built-in *chat* functionality integrated to be map view to enable synchronous communication between peers and other users of the environment. The chatters can be picked up from the map view by clicking the dots representing users. The number of participants in the discussion is unlimited, but one person may use only one chat channel simultaneously. Figure 1 shows an example of the use of chat. In addition to synchronous discussions, EDUCO uses two types of document-specific *asynchronous communications*: areas for general comments and hierarchical newsgroup-type discussions for meaningful knowledge building.

The *search* function of EDUCO can be used in finding persons or documents. The search is targeted to the titles of documents and names of users, both online and offline. The search results are shown in the search view (Fig. 1), but also in map view by highlighting the document with a blue rectangle, as it can be seen in Fig. 1.

The *alarm* offers each user a possibility to set "triggers" into the documents, groups and the overall system. In other words, a user can set EDUCO to alarm when certain conditions occur. This feature is useful in a case where a user searches for a companion showing interest to a certain document or topic, or wants to contact a particular person when he or she enters the system. The alarm function also enables making combinations of triggering events. Figure 1 shows an example of a combination of triggers: the alarm will beep if "Miikka Miettinen" or somebody from group 3 enters the system".

An important feature in EDUCO is the *support for forming groups*. Alarms, chat and navigational patterns can be used when screening for potential partners for group work. Another feature is a list of available (not yet in any group) participants in a Web-course. Every user can form a group by dicking a button "Add a new group". Other people can join an already existing group, or they can start a new group. After producing a joint work, it can be published in EDUCO for comments.

The group-forming feature of EDUCO is designed for Web-courses where the learning process involves writing reports in groups. Document icons in the "map view" of EDUCO can each represent a collection of student reports.

Empirical evaluation

Study setting

A valuable feature in systems like EDUCO is that they make it possible to accumulate large amounts of interesting information through completely unobtrusive observation of the users' activities. Whenever someone moves to another page, starts a chat discussion, joins a group, or uses any other of the available functions, the details of the event are registered in the log. This allows extensive re-construction of the conditions under which the action took place, and facilitates the analysis of the users' behavioural patterns as they occur in real-life e-learning situations.

The data set was collected during the Spring 2002 semester from a course entitled "Computer Uses in Education" with a subtitle of "Web-based learning"'. The course was given at the Department of Computer Science, University of Helsinki, Finland. The course was a web-based course without face-to-face meetings and the use of EDUCO was mandatory. Forty-six students were active in the course. Some of the students were adult learners with varying backgrounds and degrees but most of them were Computer Science majors.

The format of the course was unique compared to the other courses at the Department. The students had nine weekly reports to produce from nine different topics. It was not allowed to produce the report alone. At least a working pair was required, and a group of three was also recommended. Moreover, the groups were not allowed to stay the same during the course. A student had to be involved with at least three different groups.

Apart from the documents containing the reports of the student groups, the documents in EDUCO map discussed the issues covered during the first eight weeks. The documents were organized to eight different clusters under a common theme. The themes were close to the weekly topics but not completely the same. The document cluster sizes varied from two to ten, giving a total of ca. 40 documents. The exact amount of documents varied during the course, since new resources were added occasionally.

Results

In this paper, our empirical analysis focuses on social navigation and the formation of groups. We first attempt to examine if the presence of one or more users around a certain document attracts others to navigate to that document as well. This is the real-time aspect of social navigation as implemented in EDUCO. As stated earlier, the document icons also change their brightness/colour based on their popularity. In order to evaluate the role of the colouring mechanism, we compare overall navigation patterns to periods when a new weekly assignment was published so that the colours had not yet changed to influence the users by guiding them to the most relevant documents.

The idea of our analysis of real-time social navigation was to compare the frequencies and lengths of visits to documents that were already being read by at least one person ("occupied documents"), and visits that started without there being others present at the particular document ("unoccupied documents"). Only a rough indication of the tendency of people to move together could be obtained this way, since there were other factors with obvious effects on the results. In particular, the assignments given during the course directed most of the activity to a small number of documents, making social navigation almost unavoidable during the busiest periods. The validity of data gathered from a real course more than compensates for the lack of control, however, when it comes to evaluating the usefulness of a real system.

In order to calculate the relevant statistics, we re-constructed the navigation activity that took place during course from the log file. This involved stepping through the log one row at a time and moving users from one visitor list to another the way they moved when they were actually using the system. The number of visits to occupied and unoccupied documents as well as the lengths of the visits were computed along the way. Our hypothesis was that occupied documents would be somewhat more popular than unoccupied ones. Another intuitive guess was that visits to occupied documents would be shorter, because people would go and take a quick look at things that others seem to find interesting.

Table 1 shows the main results of the re-construction. The 48 students are sorted into 5 groups according to the distribution of their visits to occupied and unoccupied documents (group 5 has 8 students and the other groups 10). The last row of the table contains the overall figures for all students.

	Occupied % of visits	Occupied Average length	Unoccupied % of visits	Unoccupied Average length
Group 1	60%	11	40%	8
Group 2	53%	11	47%	7
Group 3	49%	10	51%	5
Group 4	43%	9	57%	5
Group 5	32%	10	68%	5
All	48%	10	52%	6

Table 1: The number and average length of visits to occupied and unoccupied documents.

The numbers in Table 1 do not indicate a preference to occupied documents over unoccupied ones, since the proportions are practically equal in all groups. The minor differences in the average lengths of the visits do no justify any conclusions either. Therefore, the log data did not provide support for our idea of the usefulness of real-time social navigation.

Another essential mechanism for social navigation is the colouring of the document icons according to their popularity. During the course, there were almost always some documents shining brighter than the others. Since they were generally the most relevant documents for the weekly assignment, the amount of guidance provided by the colouring could not be assessed in isolation under normal conditions. However, after a new assignment was published, there was a period of a few hours, during which the documents that had just become important did not stand out yet. Our analysis is based on comparing the navigation patterns observed during the first six hours following the publication of an assignment to the average patterns of the entire course.

According to our hypothesis, visits should be shorter on average when the colouring does not guide the users directly to the most useful documents. Unfortunately, it turned out that this is not the case. The average length of a visit was 7.5 minutes for periods following the publication of an assignment, and 7.2 minutes in the whole data set. From an intuitive point of view, colouring should help finding relevant documents, but as in the case of real-time social navigation, the log data did not provide support for our intuitive views.

Conclusions

The paper presented a system for collaborative Web-based learning that supports social navigation and described a real-life situation where it was used. Common wisdom has been that allowing a user to see the navigation steps of other users has an effect to the navigation of the user, although valid empirical evaluations are somewhat lacking. However, the effects of synchronous and asynchronous features of social navigation in EDUCO appeared to be non-existent in this study. The result was surprising, especially when a previous study with the same system (with less functionality) showed slightly opposite results (Kurhila et al. 2002). Further studies are necessary toseparate the effective factors.

Obtaining Realistic Information on the Context of Use of E-learning System

Masaaki KUROSU*[1] and Hideaki TAKAHASHI*[2]
National Institute of Multimedia Education
Japan
PFD00343@nifty.com *[1] hide@nime.ac.jp *[2]

Abstract: By applying the fieldwork methods such as the interview and the observation, we started our study for obtaining more realistic information about the context of use of e-learning system for the purpose of establishing the full list of system requirements. The information derived from the fieldwork will surely provide us more realistic requirement of the future e-learning system.

Introduction

Besides the university students, there are many people who would like to learn something more than they have learnt at the university or at the high school. Different from the university students, people working in the office, people working at home or people who have retired spend their lives in a variety of situations. In order for the e-learning system to be more usable, effective and satisfactory to these people, it has to be flexible and adaptive for their context. In other words, we have to obtain the contextual information on how they are spending their life in order to clarify the requirements for the e-learning systems in terms of the time course, the contents and the use of media. Although we have many research results on the requirements for the e-learning system quantitatively, most of them are based on the questionnaire. It is frequently pointed out that the questionnaire and the statistical analysis based on the quantitative data such as the questionnaire reveal just a part of the whole requirements. This is the reason why we conceived of applying the fieldwork techniques to specify the context of use information of people who have the need for e-learning.

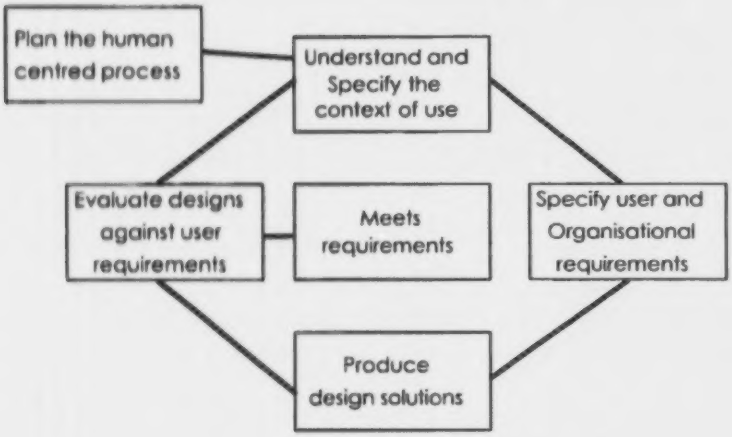
Importance of Context of Use Information

In ISO standard numbered 13407 (ISO 1999), i.e. "Human-centered design processes for interactive systems", it is clearly stated that the interactive systems should follow the design process as follows (Figure 1).

a) to understand and specify the context of use
b) to specify the user and organization requirements
c) to produce design solutions
d) to evaluate designs against requirements

In the standard, the context of use is defined as "user, tasks, equipment (hardware, software and materials), and the physical and social environments in which a product is used". It is undoubtedly necessary and important "to understand and specify the context of use", because this process is positioned at the top of all processes. Because the system design should put an emphasis on the traceability, the information specified at the first process should be kept and followed by subsequent processes. This is the prerequisite for an interactive system to be usable, i.e. effective, efficient and satisfactory.

Of course, the e-learning system is no exception. If we don't have the adequate information about the context of use of the e-learning system, the system might not fit to the user's needs and situational requirements.



Plan the human centred process
Understand and Specify the context of use
Evaluate designs against user requirements
Meets requirements
Specify user and Organisational requirements
Produce design solutions

Figure 1: Human centered design processes for interactive systems in ISO 13407

Field Work Methods

Based on ISO13407, a Technical Report ISO TR16982 (ISO 2000) "Ergonomics of human-system interaction — Usability methods supporting human centered design" was issued in order to recommend adequate usability methods for each of the design process. This TR includes such methods as the observation, the performance-related measures, the critical incidents, the questionnaires, the interviews, the thinking aloud method, the collaborative design and evaluation, and the creativity methods for supporting the design processes proposed by ISO13407.

Among them, the interview and the observation are especially recommended for the first process for obtaining the contextual information. Although these methods was developed and have been mainly used by the ethnographers in their fieldwork, their importance and effectiveness are now recognized in the field of HCI (Human Computer Interaction) as two of the main methods for designing interactive systems. Thus it is expected that the use of such methods will fulfill the list of requirements for the e-learning system that is now insufficiently and poorly filled with because of the previous use of the quantitative methods such as a questionnaire.

Focus of Interview and Observation

Before starting to obtain the information on e-learning system by the use of interview and observation, we considered about the focal points as follows.

(a) Demographic characteristics – age, gender, occupation, academic background, etc. as the basic general information.

(b) Current situation – activity in terms of the temporal and spatial dimensions, i.e. how the user is spending his/her time of the day, and the days of the week in which location (home / office / public places, etc).

(c) Expected carrier path – if the user have a clear image of his/her life in the future, e.g. to get a job, to become a social worker, etc.

(d) Obstacles – what kind of barriers there are

(e) Other – any additional information

Obtaining Realistic Information

For the purpose of obtaining realistic information, we thought that the interview and the observation should be conducted in the real field of the user as far as possible. This is similar to the concept of the contextual inquiry method proposed by Beyer and Holtzblatt (1998). Natural artifacts around the user will ease the user and will give us more realistic information, thus it was decided that the interview and the observation will basically not be held in the experimental settings but in the real life situation.

Trial Research

We started our study by applying the fieldwork methods to a housewife who has just started attending some e-learning courses. As far as we knew from our earlier study: she has graduated the doctoral course but not yet obtained the Ph.D. She is busy now for taking care of her children of 3 years and 8 months. Hence,

7:00	Wakes up in the morning	19:00	Comes back home
7:15	Child care	19:15	Child care
7:30	House work	19:30	Dinner
7:45		19:45	
8:00		20:00	Child care
8:15	Child care	20:15	
8:30		20:30	
8:45	Takes the child to nursery school	20:45	
9:00		21:00	
9:15		21:15	
9:30		21:30	House work
9:45		21:45	
10:00	Comes back home	22:00	
10:15	Child care	22:15	
10:30		22:30	Accesses the mail software
10:45		22:45	
11:00	House work	23:00	
11:15		23:15	
11:30	Puts on the PC	23:30	
11:45	Accesses the mail software	23:45	
12:00		0:00	Accesses UCLA e-learning site
12:15		0:15	Starts e-learning
12:30	Lunch	0:30	
12:45	Accesses UCLA e-learning site	0:45	Submits an assignment
13:00	Starts e-learning	1:00	
13:15	Visits the discussion board	1:15	Visits the discussion board
13:30		1:30	
13:45	Child care	1:45	
14:00		2:00	
14:15		2:15	
14:30		2:30	
14:45		2:45	
15:00	Access UCLA e-learning site	3:00	Goes to bed
15:15	Starts e-learning	3:15	
15:30		3:30	
15:45	Reads the course documents	3:45	
16:00	Homework	4:00	
16:15		4:15	
16:30		4:30	
16:45		4:45	
17:00		5:00	
17:15		5:15	
17:30		5:30	Child care
17:45	Goes to the nursery school	5:45	
18:00		6:00	
18:15		6:15	Goes to bed
18:30		6:30

Table 1: Timetable of a housewife who is learning by UCLA web site

her studying time is separated during the day and she sometimes accesses the course during midnight (e.g. 2-3 AM) as can be seen in Table 1 and Figure 2. She frequently studies the course material on the bed or on the dining table as well as in front of the PC. But she has a strong motivation to get a position at the university in the near future and this motivation lets her cope with the difficult situation for learning.

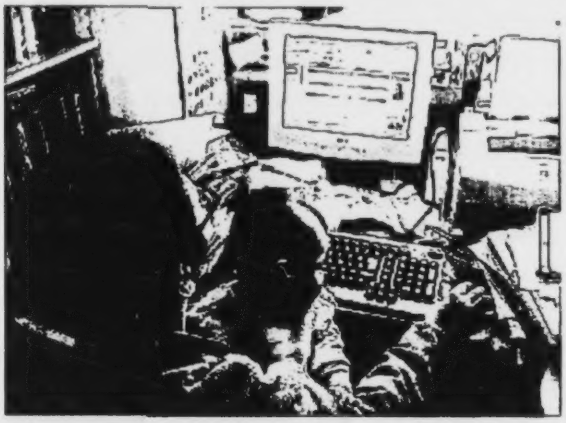

Figure 2: The situation of the housewife using her PC

Future Direction

We are planning to start some other researches for students of broadcasting university courses and the e-learning courses as well as to continue the study with this woman. It is expected that we will be able to summarize the information to propose a sufficient list of requirements for the future e-learning system.

Managing Time Thresholds in Mixed-Initiative Learning Environments

Dimitris Lamboudis, Anastasios Economides
University of Macedonia

Abstract, The effectiveness of pedagogical agents, in terms of their believability and adaptivity, in mixed-initiative learning environments can be considerably affected by the "timing" of agents' actions. This paper describes an approach to manage time thresholds, which takes into account the response "style" of each individual learner. The proposed approach has provided very positive results in the context of an agent-based, mixed-initiative learning environment, which we are currently developing.

Introduction

Mixed-initiative problem solving lies at the heart of knowledge-based learning environments, aiming to provide an individualised learning experience. Learning environments, which are inhabited by animated pedagogical agents, constitute one of the most prominent paradigms of mixed-initiative systems (Johnson, 2000), (Johnson et al, 2000), (Andre et al, 1999). While learners are actively engaged in problem solving activities, agents monitor their progress and provide to them feedback which is according to their individual profile, aiming to increase learning effectiveness and efficiency. Typical scenarios include an introduction to the subject by the agent, followed by a test, or a task to be accomplished, to evaluate the learner's level of knowledge acquisition (Lester et al, 1999). While the learner tries to perform the task in hand, the agent monitors his/her actions, and continuously evaluates various factors in order to engage and assist. The pedagogical agents' potential to couple feedback functionalities with a strong visual presence, makes them an ideal examp le for studying mixed-initiative interactions (Shaw et al, 1999).

Mixed-initiative systems must consider a set of key decisions in their effort to support joint activity, including: *when* to engage learners with a service, *how* to best contribute to solving a problem, *when* to pass control back to users, and *when* to query users for additional information (Horvitz, 1999). In order to reach to *situated* decisions, agents make "guesses" about learners' needs. These "guesses" usually depend on the evidence obtained through the "keyhole" of the user interface, collaborative statistical data about the learner (Zuckerman and Albreciit, 2001) and explicitly asked information, most commonly in the form of a query the user has to go through in the beginning of a session.

Moreover, in the context of such systems, there are many additional parameters and principles that should be taken into account by the agent in order to reach a turn taking decision (Horvitz, 1999), (Lester et al, 1999), (Bates, 1994). For example, the personality and the emotional state of the agent, the advisory history, the idle time elapsed etc.

This paper focuses on a specific aspect of agent behaviour in this context, namely *timing,* which is directly connected (among others), to *time thresholds.* Time thresholds are defined as the amount of time the learner is allowed to spend in order to successfully complete a task without the agent's help.

Idle time is one of the main variables used by the agents to infer that the learner has difficulties in understanding, solving and, in general, successfully proceeding in the learning procedure. Idle time is usually defined over a predefined time threshold, i.e. agents compare the time elapsed until the learner response, with a predefined time threshold. The actual value of this threshold is most of the times derived from statistical data and corresponds to the "mean time" that learners spend for the completion of the particular task (Lester et al, 1999).

It can be argued, however, that this approach has two main limitations:

- The pattern of the agent's behaviour is soon revealed to the student; this fact may considerably compromise agent's believability, and therefore, agent's effectiveness (Lester et al, 1997a).
- It does not take into account the individual learner's characteristics (it is rather targeted to the "average learner"), which is the main objective in personalized learning environments (Sampson, Karagiannidis, Kinshuk, 2002)

This paper proposes an alternative approach for managing time thresholds in agent-based, mixed initiative learning systems. The proposed algorithm takes into account the response of each individual learner, and has provided very positive results in the context of an agent-based, mixed-initiative learning environment, which we are currently developing.

The Proposed Algorithm

Our approach attempts to overcome the limitations identified in the previous section. The algorithm, instead of spontaneously engaging the agent when idle time exceeds a predefined time threshold, allows the learner to have "a second chance" by extending the threshold. This second chance (the extension of the predefined time threshold) is not provided unconditionally, since this would be equivalent to just set another rigid threshold, although greater than the initial one. Instead, when the threshold is reached, the agent decides to extend it by some probability P_e and not to extend it by some probability $P_a = 1-P_e$. Thus, in the "worst case", the agent will behave conventionally, i.e. like in the existing systems. However, there is a possibility, which is partially defined by the designer, at least as far as the initial value of P_e is concerned, that the agent will give the learner a second chance. Yet, if this possibility is heavily depending on the initial value of P_e, it would be just another ad hoc intervention of the designer, lacking any adaptive characteristics.

Instead, the probability of extending the time threshold (i.e. the definition of P_e), is determined by the agent, through the algorithm which checks if this extension of time has any affects on the learning procedure, that is, if it helps the learner to achieve his/her goals. In case it does, it reinforces the value of P_e. In the long run, this means that independently of the initial values of P_e and P_a the system will favour the option that actually helps the learner.

In more detail, the algorithm is shown in (Fig. 1). The corresponding notation and assumptions are as follows:

- A learning procedure that can be represented by a set of n hierarchically ordered Tasks, $T=\{T_i, i=1... n\}$;
- A set of corresponding time thresholds, $t=\{t_i, i=1... n\}$;
- An initial value of P_e^0 (the corresponding $P_a^0 = 1- P_e^0$);
  Where $P_e^0= P$ *(extend time threshold in* $T_1 \mid t> t_1$*)*, i.e. the conditional probability of extending the time in the first task, given that the time threshold has been reached;
- A constant ?p to represent the reinforcement of P_e^{i-1};
  Where $P_e^{i-1}= P$ *(extend time threshold in* $T_i \mid t> t_i$*)*, i.e. the conditional probability of extending the time in the i_{th} task, given that the time threshold has been reached;
- A constant ?t to represent the extension amount of the time threshold; (Both ?p and ?t can be either constant values or percentages);
- A Boolean *e*, to serve as a flag to declare if there has been a time extension $e=1$ or not $e=0$;

Given these assumptions the algorithm receives t_i and P_e^{i-1} as input and process them as follows:

```
While (there is no positive response) Do
    if (e=1) then
        act and proceed to Task ($t_i$-?t, $P_e^{i-1}$)
    else
        If ($t> t_i$) then
            $t_i= t_i$+?t by $P_e^{i-1}$ and e=1;
            act by $P_a^{i-1}$ and proceed to Task ($t_i$-?t, $P_e^{i-1}$)
end while
if (e=1) then
    $P_e^i = P_e^{i-1}$ + ?p
    $P_a^i = 1- P_e^i$
Next Task ($t_{i+1}$, $P_e^i$)
```

Note that in case of action-taking by the agent, the algorithm remains to the same task but with a decreased threshold. Since the learner has received help he/she should be able to complete the task in less time. The agent is assumed to provide exhaustive help if needed; thus the algorithm ends with a positive response and avoids stack overflow.

The proposed algorithm can overcome the shortcomings of existing approaches:

1. The use of probabilities, instead of a predefined time threshold, increases the possibility that the agent behaviour will not be revealed to the learner, thus the believability of our agents can be enhanced.
2. Moreover, the time thresholds are dynamically adapted to the individual learner response, thus contributing to a learning experience which is driven by the learner characteristics

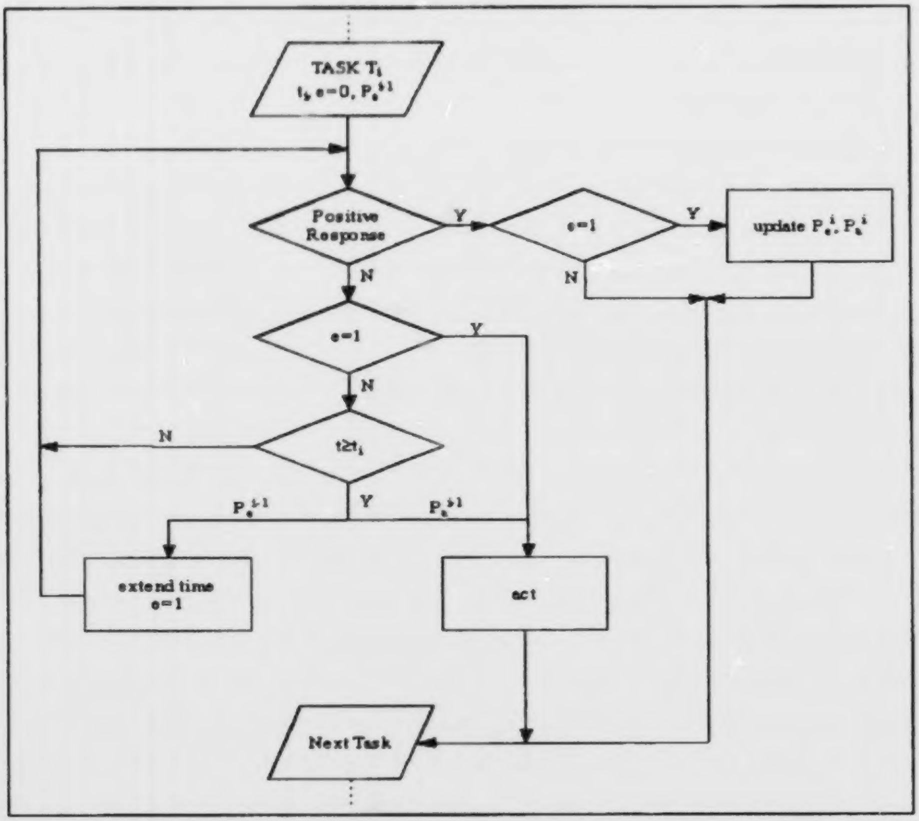

Figure 1: The proposed algorithm for managing time thresholds in agent-based, mixed-initiative learning systems

It is important to note that:

- The algorithm controls *when* an intervention will occur and not if the intervention will take place or not. The agent *will*, after all, engage if needed. Thus the algorithm maintains the pedagogical mainstream of decisions but introduces small variations to adapt to the particular user's style.
- The case of decreasing the value of P_e is not concerned. It seems rational to do so if the agent receives positive feedback before the threshold is reached but this would have the affect of balancing the value of P_e close to the initial value thus cancelling the adaptivity of the algorithm. After all, in the worse case, the agent will wait a bit longer before acting.
- Keeping the sequence of P_e ascending may lead to a value close or even equal to the unit ($P_e = 1$). This should not be avoided in general, since it actually means that the need of the user for extra time is very strong. However, in order to maintain the second characteristic of the algorithm (hiding the behaviour pattern), the designer could incorporate a control for the upper limit of the value of P_e.

Discussion

This paper has proposed an algorithm for managing the "timing" of agents actions in the context of mixed-initiative learning systems. The idea of the algorithm is to modify the timing of agents interventions, based on a probabilistic model, which takes into account the responses of each individual learner.

The proposed algorithm is being implemented in the context of an agent-based, mixed-initiative learning environment that we are currently developing. We have conducted some preliminary experiments with students of our department to evaluate the algorithm. In particular, we interviewed students using the system with pre-defined time thresholds, against students using the system where thresholds follow the proposed approach. This informal evaluation provided very positive feedback: the fact that agent's behaviour cannot be easily determined by the students, makes the agent believable, and enhance their learning effectiveness.

Hard Choices: Selecting a Course Management System

by Bruce Landon, Ph.D.

Choices are difficult because there are *too many products*

The situation is reminiscent of the early automobile industry when there were over a hundred automakers. Like the early auto industry many other competitors will not survive in the long run. The current front-runners: WebCT and BlackBoard started out as small almost personal projects a few years ago and are now multi-million dollar enterprises that span the global education marketplace. There may well be others out the current products that will evolve into the major brands of tomorrow as the market matures. The point of this analogy is that selecting a learning management system is much more complicated than selecting a new car, in part, because there are so many competing models. There are over 100 products in this marketplace that range from relatively simple limited function applications like WebBoard which just provides threaded discussions and chat to complex enterprise wide learning systems that link to backend databases and administrative data systems used by colleges and universities. Previously in 1997, I had attempted to characterize these products as components or suites by this categorization turned out not to be useful because there were so many variations from product to product he became difficult to classify new products. Also, the products in this marketplace evolve quite rapidly with a new model or version almost every year, like automobiles. So to deal with this rapidly changing market it seems better to characterize products in terms of the features that they provide.

Too little working memory in decision-makers

Nobel laureate, Herbert Simon (1979) characterized the human decision making capacity as having "Bounded Rationality" (also see Gigerenzer & Selten, 2001). When people face decisions they operate within the bounds or capacities of the human mind. They are limited by fallible perceptions, wandering attention, faulty memories, and fluctuating information-processing abilities. People don't optimize, but instead resort to simplifying rules of thumb in order to proceed with their decision-making. These limitations have been investigated for decades with the repeated finding that working memory limitations play a major role in limiting the ability to make rational decisions.

When facing difficult decisions, people encounter overload and then they resort to ways of coping that involve cognitive shortcuts. When overloaded, they are more susceptible to cognitive illusions (Kahneman and Tversky, 1996). Cognitive illusions are similar to perceptual illusions in that they stem from the fact that in both types of illusions the person can focus only on a small part of the situation at one time. In the case of perceptual illusions this is because the fovea of the eye that sees fine detail encodes only a small segment of the spatial panorama at each fixation. In the case of cognitive illusions this is largely because the conscious working memory can hold only a few "things" and the rest must be inferred or extrapolated in ways that are sometimes biased. In both types of illusions the person is not necessarily aware of any "illusion" at all and may believe that they are "seeing everything correctly."

Too many Cognitive Illusions in Decision-Making

The discrepancies associated with cognitive illusions may be seen a little more clearly in contrast to an idealized rational decision process. In the idealized process, one starts by selecting relevant features/criteria and then assigning an importance weighting to each of those features. Next one evaluates each choice option on each of those important features and assigns a suitability score. Finally one makes the rational decision to choose the option with the highest weighted average suitability score (the average of the weights for a feature multiplied by the feature's suitability score). Choosing the option with the best score is the rational decision (Keeney and Raiffa, 1976 as cited in Roe, Busemeyer and Townsend, 2001). With only a couple of optional choices and a few important features it is likely the limitations of working memory would be overwhelmed even if one were able to do the mental multiplication part. When one is overwhelmed by the size and complexity of the decision situation then one is susceptible to a host of cognitive illusions. A few of the major ones are: Availability Heuristic, Representativeness Heuristic, Hindsight Bias, Gambler's Fallacy, the Framing Effect, Similarity Effect, Decoy Effects, and Overconfidence Effect. When the decision situation is simple and small, on the other hand, most people can and do make good judgments unaffected by these cognitive illusions.

Making the decision situation smaller and simpler can circumvent these obstacles. Dividing up a complex decision into several small and simpler decisions keeps the load on working memory within normal capacity and then decision makers can be quite rational in making good decisions. Donald Norman (1999) has made the case that human-computer interactions can and should be designed to take account of normal human fallible perceptions, wandering attention, faulty memories, and fluctuating information-processing abilities. With good design of decision-making processes that keep the in-the-head part small and simple, a system can be optimized to enable quality decision-making. The normative weighted averaging strategy can be easily divided up into small and simple component parts and then later recombined (outside-of-the-head) into a rational decision process that leads to the "best option." There is a powerful decision-making synergy in combining the focused judgmental prowess of people with the memory and computational prowess of computers.

How people normally Make Decisions: The 5 Basic Strategies

There are five basic decisions strategies (Payne & Bettman, 2001) for choosing among options (products, services etc.) based on features or aspects of the options. All of these five strategies are compromised by the reality that the set of options is limited to those known to the decision-maker and the "best" option may be simply missed in the whole process. While the names of these strategies on may be unfamiliar is quite likely that everyone has used all of the following strategies at one time or another:

One Reason strategy (aka lexicographic, pick the best)
Elimination by Aspect strategy (aka pick the last)
Satisficing strategy (aka Bounded Rationality Model)
Equal Weight strategy (aka scoring strategy)
Weighted Averaging strategy (aka weighted adding strategy, grading model)

The One Reason strategy involves two steps: selecting the most important feature and then picking the product from all of the options that is best on that one feature. There is no requirement for the features to be expressed as numbers. If there is a tie then the decision maker simply repeats the process on the second most important feature. This non-compensatory strategy does not allow for some features of an option to make up for other less adequate features. The only involvement of a second feature is in the case of a tie that is broken by considering the next most important feature and selecting the option that is best on that feature.

The Elimination by Aspect strategy is a simple screening strategy involving two steps: setting the requirements for each of the features and then eliminating options one at a time which do not meet any one of the requirements. The decision maker examines the features of each option one by one and the option is eliminated as soon as a feature is found that does not meet the requirements. This popular strategy does not need for the features requirements be expressed as numbers and is easy-to-use. The elimination by aspect is a non-compensatory strategy so that once an option is rejected on any feature that option is eliminated from further consideration. This strategy does not necessarily result in a single best option since more than one option may pass on all of the requirements. Including any features that are irrelevant or biased in favor of one of the options compromises this process.

The Satisficing strategy (Simon, 1955 cited in Gigerenzer and Selten, 2001) is more psychologically developed model of sequential decision-making that includes setting requirement cutoff levels for each feature. An option is examined until it fails to meet one of the cutoff levels then it is rejected and the next option is considered. The first option that passes on all of the features is selected. If none of the options pass all of the cutoff requirements, then the requirements are reduced to new lower cutoff levels and the process is repeated. The satisficing strategy is non-compensatory and effected by the order in which the options are presented as well as the aspiration level of the initial cutoff requirements.

The Equal Weight strategy is comprehensive and considers all of the features on all of the options. The suitability values of one (passed) or zero (failed) are assigned to each to each feature on each option. The total suitability score for each option is the simple sum of the feature suitability values for that option (all features are weighted equally). The option with the highest sum of the values is selected. This strategy is directly analogous to multiple choice test scoring where correct answers are awarded one, wrong answers are awarded zero, and the highest sum score identifies (selects) the best student on the test. This compensatory numeric strategy enables some features assigned one's to compensate for other features that were assigned zero's. This strategy is more useful when there are many features because there is less risk of a tie for best score.

The Weighted Averaging strategy is a more complex version of the simple sum score model where each feature is also assigned an importance weighing. This idea implies that the decision maker is willing to make trade-offs to arrive at the selected option. The process involves five steps: (1) setting the importance weights for each of the features, (2) for each option then determining the numerical suitability value for every feature, (3) multiplying the feature suitability value times the feature weight, (4) then summing these weighted features subscores into an option total score, and (5) finally selecting the option with the highest average score. The averaging of the weighted option total scores simply returns the scores to the scaling metric of the feature suitability value units (which are often on a rating scale such as 1=poor to 9=excellent). This strategy is directly analogous to the grading model where different parts of the grade are weighted differentially (or subsections of an exam are weighted differentially) to arrive at the final mark. The weighted averaging strategy is compensatory in two ways: high scores on one feature compensate for low scores on another feature and a lower importance weight on one feature is compensated for by a higher importance weight on another feature. This strategy is less likely to result in ties between options than is the equal weight strategy when using a relatively small number of features. Furthermore, the weighted averaging strategy is considered the normatively rational decision process because it uses all of the information available in a consistent manner to arrive at a selection. This model is similar to the multiple linear regression model used in statistical analyses and suffers from some of the same shortcomings, most notably it is compromised when irrelevant features are used and when unreliable suitability values are used.

Decision makers often make use of combinations of the above strategies. In combined strategies the decision is made in phases. The initial phase is often to screen out some of the potential options in order to reduce the complexity of the situation to as short list of options. This phase is followed by a more thorough consideration phase to select the best option from a short-list of candidate options. The primary reason that everyone does not use the weighted averaging strategy all the time for all decisions is because it would be too mentally difficult and too time consuming. Other strategies are heuristic attempts to make good decisions with less effort and in less time and sometimes they seem to work well enough.

Thinking in terms of product features

Within each of the three audiences the features of the products can be further grouped into clusters of features and this can reduce the complexity further. On the Online Educational Delivery Applications site (http://www.edutools.info/landonline/) the following conceptual groupings have been used to provide targeted views for the learners, learner support, and technical administrator audiences respectively:

Learner Tools (for learner audience)
    Communication Tools
    Real-time Tools
    Productivity Tools
    Student Involvement Tools

Support Tools (for learner support audience)
    Administration
    Curriculum
    Instructor

Technical Specifications (for technical administrator audience)
    Pricing/Licensing
    Standardization
    Technical Administration
    Hardware/Software

Within each of these conceptual categories there would be a small number of specific application tools or features. Altogether there were 52 such specific features that could be a part of an individual application. The complete listing of application features inside of the above conceptual structure attempts to organize the otherwise overwhelming list of features: (adapted from http://www.edutools.info)

No product had all of the possible features and no institutional situation needed all of the features either. The Online Educational Delivery Applications site was intended to help institutions find products with the features that they need and for vendors of products to be discoverable on the basis of the product functionality in the context of a rapidly developing marketplace. The list of product features also turns out to be a moving target over time as new technologies are incorporated into the evolving applications.

Screening phase of decision-making based on requirements of Individual Situations

The elimination by aspect strategy is a screening strategy involving two steps: setting the requirements for each of the features and then eliminating options one at a time which do not meet any of the requirements. To be able to decide which features are important the conventional approach is to conduct some sort of needs analysis of what is required in the institutional setting. This analysis often reveals the uniqueness of the needs of the future users of the online system. At this stage it can be beneficial to involve the stakeholders: students, faculty, student support personnel, and the technical administrators to gain later acceptance of the eventual decision as well as to become aware of needed features that might have been otherwise overlooked. Politically it can be beneficial to even involve representatives from the governing board of the institution when this decision will represent a new pedagogical direction or is expected to involve significant long-term resource commitment.

Making a Short List of Application Options

Using the web tool described above greatly speeds up this elimination by aspect process for those applications that are reviewed on the site. The elimination by aspect is a non-compensatory strategy so that once an option is rejected on any feature that option is eliminated from further consideration. This strategy does not necessarily result in a single best option since more than one option may pass on all of the requirements. The usual outcome of the elimination by aspect strategy is to result in a short list of possibly acceptable options that become the narrowed focus for a more discriminating decision strategy. It may be prudent for comparison purposes to include in the short list any applications that are used by consortia where the local institution is a member or in the case of community colleges the application that is used by local universities where the college has special relationships.

Evaluating product suitability as part of the weighted averaging strategy

Evaluating products (or externally hosted product options) can be a very large task. The greater the number of products and the greater the number of important features multiplies quickly into a potentially overwhelming product research task. This task can be partially shifted to the vendors by structuring a competition among the likely candidates where they are invited to bring the information to the decision makers rather than the decision makers seeking out the vendors and trying to find out the most current product information. The market has matured enough so that most vendors are capable of responding to a request for proposal (RFP) to supply the desired product functionality. Many institutions already have RFP procedures but may never have used them for a situation as complex as selecting an online educational delivery application.

Inviting the shortlist of vendors to competitive presentations/proposals (RFP model)

The RFP model has been described for web software acquisition recently (http://www.technologynews.net/rfp/infotech_rfp.doc) as a necessary part of the decision process. The RFP model offers several advantages over less formal product selection processes including: all vendors get the same information and have a fair opportunity to compete while the decision makers get a proposal document that can be used to assess both the vendor interest and competence. The RFP would be sent to the short list of possible vendors. The vendors will likely have questions as they prepare their proposals so it is useful to have a designated contact person who can supply consistent clarifying information to all of the vendors' requests for information. When the proposals are received there is often another round of elimination by aspect strategy to determine which proposals are in the competitive range. The US Department of Defense (http://web.deskbook.osd.mil/reflib/mfarsups/072ua/009/072ua009doc.htm) further advises that a proposal may be considered outside of the competitive range if (1) it does not address the essential requirements, (2) has a substantial technical drawback the would essentially require a new proposal to fix, or (3) the proposal contains major deficiencies, omissions, or out-of-line costs. They also advise that these proposals are part of a negotiation process and at the end of negotiations, the competitive vendors should be provided with one additional final opportunity to submit a revision known as the "best and final offer."

The RFP method is a time-consuming and involving process both for the institution and for the potential vendors that can be used to produce a fair vendor competition where the best candidate is selected and the social goals of rational decision-making are accomplished. The Online Educational Delivery Application site provides web tool support for the Weighted Averaging Strategy calculation part of the of decision-making. This decision engine tool is little more than an automated score sheet that combines the feature importance and the feature suitability scores into an appropriate total product score. The tool does however enable the decision-makers to use the most rational strategy of decision-making, which would be impossible to do in one's head. The following example illustrates the decision engine web tool using two vendors (WebCT and BlackBoard) with three features (accessibility for persons with disabilities, student help, and instructor help).

Developing, Delivering, and Managing Legal Compliance eLearning Courseware in a Corporate Environment

Teresa Lau
Sun Microsystems Inc.
Menlo Park, CA
USA
teresa.lau@sun.com

Abstract: The paper describes Sun Microsystems' implementation and management of a mandatory online legal course, Business Conduct Overview, for a global, corporate wide audience beginning in July 2002. Sun created an eLearning environment to help employees access customized content, track their progress, report course completion, assess content comprehension, and send e-mail reminders to employees who haven't completed the mandatory training. The various components of the eLearning environment, implementation of the online course, and future plans for delivery and management of online legal compliance training at Sun are discussed.

1. Introduction

Throughout its 20-year history, Sun Microsystems has committed itself to the highest standards of business integrity. Because of increasingly complex legal and regulatory environments in the many countries in which Sun does business, Sun must make every effort to promote its employees' compliance with standards of business conduct. To raise employees' legal and ethical awareness and provide them with resources they need to make the right decisions and take effective actions, Sun's Business Conduct Office has developed an online learning course that is mandatory for all salaried employees to complete. To provide an easily accessible and effective eLearning environment, Sun Microsystems developed a suite of tools to deliver and manage online learning. The eLearning environment includes several unique features, such as the following:

- Automatic e-mail notifications to employees and their managers regarding scheduling and completion of mandatory training; e-mail reminders to those who haven't completed mandatory training
- Automatic launch of personalized content by job type, geographical location, and language preference
- Tracking and reporting
- Online quizzes to test and enhance retention and comprehension

The training is being rolled out in phases. Employees and their managers are notified when to begin the training. At present, nearly one-third of the targeted employee audience has completed the online training.

2. eLearning System Features

2.1. Automatic E-mail Notification

To accommodate the 40,000 Sun employees required to complete the legal training, the Business Conduct Overview course is being rolled out in phases that cut across organizational lines. The integration of the training system and Sun's human resources and e-mail systems allow customized e-mail notifications and reminders to be generated and sent automatically to employees and their managers when various events occur:

- An employee is scheduled to begin the mandatory training.
- An employee has completed the training.
- An employee has not completed the training although the deadline for completion has passed.

The customized e-mail messages serve as a means of communication between the Business Conduct Office and the global Sun community. This helps employees and managers take responsibility for managing their own training.

2.2. Personalized and Localized eLearning Content

To deliver customized content to employees that is tailored to individual responsibilities and needs, the system uses an up-front user profile survey to gather user information (Figure 1). The system can then dynamically generate personalized content based on an employee's job type, geographical location, and language preference.

2.3. Tracking and Reporting

User progress tracking and management reporting are two important components of the eLearning environment for legal compliance training. To enable tracking, it is necessary to authenticate the user by his or her employee login and password against the human resources database connected through the eLearning system. Once an employee has logged into the system, all activities at the course level are tracked, and completion data is automatically collected and stored. The tracking data is assembled in real time into reports organized at the employee, manager, and organizational level. Real-time user tracking and reporting has proven valuable in managing Sun's mandatory legal training.

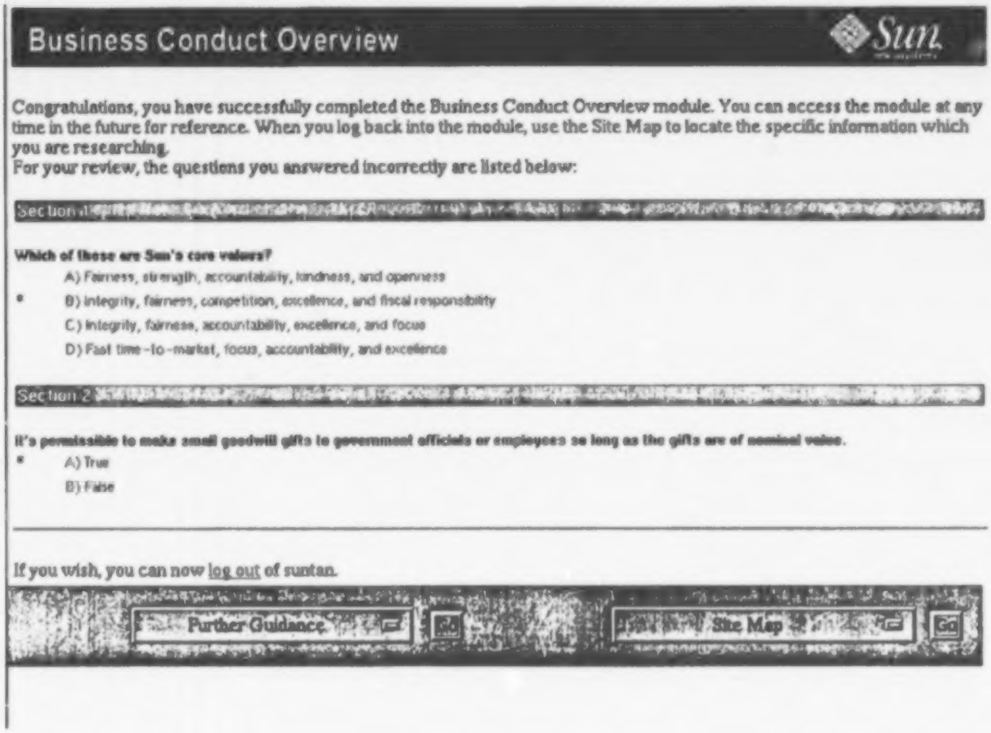
2.4. Online Testing and Assessment

To test employees' comprehension and retention of key concepts, short quizzes with feedback are embedded in each section of the course. At the end of the course, employees take a final test. After they have completed the final test, employees receive their test results with incorrect answers highlighted (Figure 2). They are also given additional references that correspond to the questions missed. The final test demonstrates the employee's mastery of content and is required for the employee to receive a completion status. The testing tool also includes comprehensive reporting features: for example, the summary scores can be used to analyze the effectiveness of the online instructional content.



Congratulations, you have successfully completed the Business Conduct Overview module. You can access the module at any time in the future for reference. When you log back into the module, use the Site Map to locate the specific information which you are researching.
For your review, the questions you answered incorrectly are listed below:

Section 1

Which of these are Sun's core values?

A) Fairness, strength, accountability, kindness, and openness
* B) Integrity, fairness, competition, excellence, and fiscal responsibility
C) Integrity, fairness, accountability, excellence, and focus
D) Fast time-to-market, focus, accountability, and excellence

Section 2

It's permissible to make small goodwill gifts to government officials or employees so long as the gifts are of nominal value.

* A) True
B) False

If you wish, you can now log out of suntan.

Figure 2: Test Feedback

3. Conclusion

Sun Microsystems has designed, developed, delivered, and managed an online legal compliance course for its worldwide workforce. Since the initial rollout in July 2002, more than one-third of eligible employees have successfully completed the mandatory training. The eLearning environment created for the delivery, administration, and management of the online course has proven an efficient, robust, cost-effective, and reliable way to deliver and manage online legal compliance training for a large enterprise. The success of online training for an internal audience will pave the way for Sun to launch the same legal training for our partners next year.

Streaming, Plug-in Free PowerPoint™ Playback over the Web

Introduction

Microsoft PowerPoint is the most popular authoring tool for creating business presentations and training content. And for good reason – it's easy to learn and to use. It supports narration, animation, transitions, embedded video, as well as the ability to hyperlink or to navigate to specific slides within a single presentation, to other PowerPoint presentations, to Web pages (URLs) and to other content.

The only problem with PowerPoint is that the output files are too large for delivery over the Internet or through e-mail, and too numerous to manage easily.

That's where ***impatica*** comes in. Simply put, ***impatica* for PowerPoint** extends the reach of PowerPoint by providing an easy to use tool for delivering PowerPoint presentations over the Internet or through e-mail. And unlike PowerPoint's "Save as HTML", "Save as Web Page" or other options for Internet delivery, ***impatica* for PowerPoint** retains the rich media functionality of your presentation

This document describes how ***impatica* for PowerPoint** works, explains how the "*impaticized*" content is efficiently delivered and highlights the resultant benefits.

Conversion for Streaming Delivery

***impatica* for PowerPoint** is a desktop software application that reads Microsoft PowerPoint files and transforms the file into an efficient streaming format that can subsequently be read and "played" by a small Java applet on the viewer's Internet device.

***impatica* for PowerPoint** dissects the PowerPoint file and identifies each audio, text, shape, and picture. Each media object is compressed or otherwise optimized for Internet delivery.

- Audio is converted to Sun AU format and then compressed using ***impatica***'s proprietary compression algorithm. (Sun AU audio is the only audio format currently supported by Java.)
- Pictures and other images are converted to GIF format (if 8-bit or less) or to JPEG format (if greater than 8-bit). JPEGs are compressed according to a Translation Option set by the content developer in the Graphical User Interface for ***impatica* for PowerPoint**.
- Pictures are further optimized by discarding any picture elements that have been removed through cropping. (Even if cropped, PowerPoint retains the entire original picture.)
- Text objects are rendered as images during the translation process. While this transformation is not necessarily optimal in terms of file size, it is a crucial step to ensure that all text will be displayed identically on all viewers' devices, regardless of hardware, OS, or browser platform.
- Wherever possible, autoshapes are retained as dimensioned objects; however, some compound autoshapes are rendered as images at translation time.

impatica* for PowerPoint** files typically achieve 90 to 95% compression of narrated, animated PowerPoint presentations, meaning that the resultant ***impatica file will be only 5 to 10% of the size of the original PowerPoint file. Note, however, that the actual compression achieved on a particular PowerPoint file will be dependent on the relative proportion of audio, text, autoshapes and image objects.

The optimized media objects are then organized into the ***impatica*** streaming file format, in the order of appearance in which the objects are required. That is, the objects required for the first slide are placed in front of the objects required for the second slide, and so on. Note that, in presentations that include hyperlinks between slides, since it is not possible to anticipate the order in which the viewer will choose to view the slides, the streaming ***impatica*** file is always organized in the physical slide order.

Wherever possible, ***impatica* for PowerPoint** will reuse objects that appear multiple times throughout the presentation. This pertains to all object types, including audio, text, autoshapes and images.

Playback in a Browser

Once translated, the ***impatica*** file must be uploaded to a Web server from which it can be played by ***impatica***'s Java applet. Specifically, playback is initiated by opening a Web page that contains HTML code pointing to ***impatica***'s applet and ***impatica*** file.

```
<APPLET CODEBASE = "appletlocation.com" CODE = "com.impatica.ImPlayer.class"
ARCHIVE = "ImPlayer.jar" WIDTH =504 HEIGHT =288>

<PARAM NAME = "FILE" VALUE="Intro">

</APPLET>
```

(Note that, if the ***impatica*** content and applet code are located in the same folder as the HTML page that invokes playback, the "CODEBASE" attribute is not required.)

When the Browser opens the Web page, it launches the applet which, in turn, opens and begins to stream the ***impatica*** content file. As soon as the first ***impatica*** objects have been received, the applet begins to display and play the ***impatica*** presentation while the remaining content objects are being streamed in the background.

Provided that the Internet connection is fast enough to stream the remaining content faster than it is required for playback, the ***impatica*** presentation will play without pause or hesitation. Normally, continuous playback can be achieved within a 2K stream, i.e., over a 28.8 kbps connection.

Note that when playing presentations that contain hyperlinks to specific slides within the presentation, pauses may occur if the viewer clicks on a hyperlink that jumps ahead several slides. The likelihood and extent of the pause will depend on the speed of the Internet connection, the "richness" of the PowerPoint content, and the number of slides jumped over by the hyperlink. However, these delays can be essentially eliminated through effective content design, using "tips and tricks" explained in the ***impatica*** for PowerPoint Users Manual.

Unlike other streaming technologies that require special server-side software to "push" the content to the browser, ***impatica*** content is read by the applet (within the browser) from any standard HTTP server. This approach has the additional advantage that ***impatica*** content will be automatically cached by proxy servers and caching network strategies thereby reducing the load on the main server. Because there is no server side software, the only playback bottleneck at the server end is the raw throughput of the server cluster and the corresponding connection to the Internet backbone.

Delivery through E-mail

Delivery of ***impatica*** content through e-mail is essentially the same as viewing ***impatica*** content from a Web page. The actual e-mail message is a small, simple HTML document that contains the <applet> tag and related information required to launch the applet and stream the ***impatica*** content from the server over the Internet.

The fundamental advantage of this approach is that the actual e-mail delivered to the recipients' inbox is tiny – generally only 2 to 3K, including all headers and addressing information. There are no bulky attachments that must be downloaded and that would typically clog up the recipients' in-box.

Only when the e-mail is opened, and as long as the user is then connected to the Internet, is the ***impatica*** content accessed and displayed as it is being streamed in from the server.

Scalability and bandwidth requirements

With reasonable content design, most narrated, animated ***impatica*** content will play within a 2Kbps stream. That bandwidth requirement is approximately the same as a well designed web page that contains a reasonable mix of text and graphics. One thousand concurrent hits to a web page that contains ***impatica*** content would require an aggregate throughput capacity of 20 Mbps, disregarding for the moment any savings that result from proxy servers or other caching schemes. That load would be well within the capability of a competent Web server. On the client side, the other important benefit of the high compression ratio is that the quality of the streaming presentation is acceptable at the very least, and high at best, over a standard modem connection (33-56Kbps).

These features represent major bandwidth advantages over other multimedia content delivery streams, such as Macromedia Flash and QuickTime or other video streaming technologies. In a large educational or corporate environment, the reduction in bandwidth can easily translate into thousands of dollars of savings on a monthly basis.

Storage requirements

Another benefit of ***impatica***'s aggressive approach to compression is a significant reduction in the amount of disk space required to host PowerPoint content on the server. On average, *impaticized* PowerPoint files require only 10% of the storage capacity for PowerPoint files, whether they are stored as .ppt files or saved as HTML or as Web pages. Because *impaticized* PowerPoint presentations are stored as simple content files on an HTTP server, without any special server-side software, there is no additional overhead beyond the actual small ***impatica*** file.

The bottom line

impatica's unique and powerful technology combined with its intuitively simple user interface delivers important benefits to anyone wishing to publish their PowerPoint presentation over the Internet:

- **PowerPoint users become empowered as online publishers;**
- **The time, cost and complexity of producing online training and other content is substantially reduced;**
- **Presentations can be delivered to the widest possible audience, without regard for hardware, OS, browser or Internet connection speed;**
- **Plug-in free delivery ensures hassle-free, spontaneous delivery.**
- **Narrated, animated, interactive rich media content provides an engaging message – people remember more when they SEE, HEAR and INTERACT with the content;**

Diabetes and Your Eyes: A Pilot Study on Multimedia Education for Underserved Populations

INTRODUCTION

The development and implementation of technology as a vehicle for instructional delivery to health care patients is on the rise (Health on the Net Foundation, 2002). More than ever, individuals are searching for more health knowledge and questioning their medical management through Internet derived mechanisms (Pew Foundation, 2002). Providers sensitive to these changes may suspect that acquired information is more valuable to patients when complimented or endorsed by their own health providers (Clement, 1995). In fact, both parties may potentially benefit, with providers saving time for education.

More recently, touch screen 'kiosks' are being investigated in clinical environments. Kiosks have been described as an easy, convenient, and preferable medium for learning (Glasgow, McKay, Boles et al., 1999). Example applications have included cancer therapy, support for individuals with brain injuries, and chronic disease management such as diabetes (Lewis, 1999). However, there are significant barriers to widespread use among vulnerable populations.

A digital divide persists in the United States, where specific low-income urban as well as rural geographic areas have less access despite overall growth in the US (National Telecommunications and Information Association, 2002). Besides having access to technology, computer skills make current applications more difficult to use (Eng, Maxfield, Patrick, et al., 1998). Few interfaces have been able to accommodate the diverse levels of capability among patients. Also, health literacy remains a barrier. In a study of 25 common health web sites, all of the English and 86% of the Spanish web sites required a high school level or greater reading ability (Berland, Elliott, Morales, et al., 2001). Health information that requires a higher level of literacy will exclude the 40 or more million Americans who are functionally illiterate. In response, recent computer applications have begun to address literacy, and subsequently received favorable responses in pilot testing (Castaldini, Saltmarch, Luck, et al., 1998).

One of the potential benefits of multimedia learning environments on patient education is the ability to target individual needs and preferences. Unfortunately, there are few quality resources available that target African-American, Latino, and other ethnic minority groups. According to Rosenthal and Bandura (1978) "attribute similarity generally increases the power of modeling influences even when the personal characteristics may be spurious indicants of performance capabilities" (p. 656). As such attending to salient characteristics of the population such as age, gender, education level, socioeconomic status, race and ethnicity can increase the impact of the learning materials (Bandura, 1997). Because multimedia environment invite the inclusion of video, users are able to see "themselves" in the educational materials, and can more easily provides appropriate modeling opportunities to minority populations where they might not otherwise be accessible.

This proposal details the development and implementation of a new multimedia application for an underserved patient population with diabetes. A pilot study was conducted to evaluate program use by participants, as well as patient attitudes regarding diabetic eye disease. The main outcome sought from using the program was to increase compliance with annual dlated eye examinations (the standard of medical care).

METHODS

Software Application Development

Prior to developing the application a needs analysis was undertaken. Research examining African-American and Latino diabetic patients was reviewed, especially regarding barriers to obtaining yearly eye examinations (e.g., Walker, Basch, Howard, et al., 1997). In addition, currently available information regarding diabetic eye disease was obtained through the National Eye Institute and National Eye Health Education Program and the Core Curriculum for Diabetes Education.

A lesson plan was created based on the ultimate objective of patients obtaining eye examinations. The lesson plan included 5 segments: (1) An introduction to diabetic eye disease (via patient testimonial), (2) A tutorial on how diabetes affects the eye, (3) A series of patient testimonials relating the barriers to obtaining eye examinations, (4) An interactive portion where the user is tested regarding the needs for an eye exam based on patient testimonials, and (5) A tour of the ophthalmology clinic where eye examinations are performed. The lesson plan was translated into Spanish by two bilingual researchers.

To complete the multimedia, digital images from the National Eye Institute were obtained. In addition, patients were recruited to provide videotaped testimonials. Consented individuals discussed their experiences with diabetic eye disease, or with eye examinations. A total of 16 African-American and 16 Latino diabetic patients were recorded in English and Spanish respectively, answering open ended questions freely without scripting. Example barriers discussed by patients included: fear, denial, religion/faith, pain, and insurance.

Clinical Pilot Testing

Patients arriving for their scheduled medicine or diabetes clinic appointments were recruited. Inclusion criteria include history of type 1 or type 2 diabetes, English or Spanish speaking, and responsibility for diabetes self-care. Consented patients were taken to the computer in the clinic and were instructed regarding the use of the touch screen. They were allowed to view the program at that time, or after their visits with their providers if more convenient. Participants were able to complete the program in approximately 15-20 minutes.

After viewing the multimedia program, a brief 20-question survey was completed regarding attitudes toward computerized patient education as well as diabetic eye disease. In addition, follow-up surveys were conducted 3 months and 6 months later by telephone.

RESULTS

A sample of 56 patients viewed the multimedia application and completed the initial survey (Table 1 includes demographic and descriptive information). Twenty-seven patients, primarily African-American (18/27), completed the English lesson, while 29 Latino patients completed the Spanish version. Overall, a majority of these subjects had no more than some high school education (70% of the English group, 83% of the Spanish group); and many had never had taken any diabetes education classes before. With respect to standard of care, only 15 (56%) of the English group and 15 (52%) of the Spanish group have undergone dilated eye examinations. Finally, many have reported limited or no computer usage previously (48% of the English group, 14% of the Spanish group).

Of the initial 56 patients, 34 responded to the 3-month survey, and 30 responded to the 6-month survey. A repeated measures ANOVA with language (English/Spanish) as a between-subjects factor was employed. When necessary the Huynh-Feldt correction for degrees of freedom was used.

In the first of these analyses, difficulty of using the computer program (1 = Very Easy; 5 = Very Hard) was used as the dependant measure. Results of the analysis indicated a significant Time X Language interaction ($F_{(2,52)} = 8.73$; $p < .01$). Examining a v-plot of this interaction, a quadratic effect for difficulty of use over time between languages was identified. Those participants who viewed the English version of the program rated computer usage significantly more difficult at the time of the three month follow-up, while the Spanish version participants maintained a consistent rating over time. Main effects for Time and Language were also significant ($F_{(1,26)} = 7.71$, $p < .01$); $F_{(1,26)} = 12.51$, $p < .01$, respectively), but interpretation was set aside in favor of the interaction.

For most of the attitude questions regarding diabetic eye disease, responses did not show a trend over time. However, significant main effects for time were observed with 'diabetes can result in blindness' ($F_{(2,52)} = 3.48$; $p = .038$) and 'you can have eye damage with no symptoms' ($F_{(2,52)} = 3.94$; $p = .025$); both with agreement lessening over time.

There was a small but significant difference between language groups with respect to attitude towards seeing the eye doctor every year ($F_{(1,26)} = 5.04$; $p = .034$). The group viewing the Spanish program were more likely to strongly agree with this item.

Finally, a significant interaction between Language and Time toward being 'afraid to see the eye doctor', ($F_{(2,52)} = 4.734$; $p < .05$). Main effects for Time and Language were not found to be significant. Examining a plot of the interaction we saw that the English group had an increase in reported fear to see the eye doctor at three months, but returned to baseline after an additional three months. However, the Spanish group remain consistent immediately following and at the three month follow-up, with a sharp increase in fear at the six month survey.

DISCUSSION

Despite common barriers to accessing health information, there was clear interest and use by the underserved patient groups represented in our sample. Most individuals felt the multimedia was 'easy' or 'very easy' to use; yet there was still a small minority who had difficulty with the English version. Some individuals expected the kiosk to act like a television, running continuously without user input. The reduced level of computer skills may increase the difficulty in actively engaging users. Unfortunately, activities that may better translate a message and provide education require more interaction than simple directions (such as touching the screen). Given the potential benefit of behavioral change, we need further research to improve the user interface.

There was a significant trend toward having greater difficulty using the program reported by subjects at 3 and 6 months. Some individuals may be more likely to report interest and enthusiasm immediately after experiencing a novel intervention. This may be an important concept to consider in additional evaluations where attitudes may change over time.

Attitudes towards diabetic eye disease and eye examinations were positive; though the study did not capture behavioral change from the intervention (the study did not include pre-testing). Differences between English and Spanish groups may represent inequalities in the program, particularly with patient testimonials. For example, some of the Spanish video sequences may stress specific ideas more strongly; or the English video clips may be less clear or influential. In either situation, the cultural differences in the program may contribute to expressing different messages resulting in different outcomes.

The data collected on attitudes post-intervention will be applied towards further development of the lesson. For example, the idea that faith alone may prevent eye disease was common in both English and Spanish groups; despite the majority disagreeing with it. Addressing faith is very important in education on prevention.

The greatest advantages cited by patients include: ease of use of the computer program, the educational nature of the audio narration, and the video testimonials of patients. Some of the users wished to unplug the headphones to so friends or family members can simultaneously view the multimedia. Having more headphones available at a kiosk may be worthwhile.

Implementation in the clinical environment is a significant challenge for interactive kiosks. Since the study has been completed, the computer has continued to collect data regarding patient usage. Further data analysis may offer solutions on how to integrate education into clinical flow. For example, prior to visiting a health provider, there is often an undesirable waiting period possibly serving as an opportune time for self-education. However, after an encounter with a provider, interest in personal health is piqued, and additional reinforcement via the computer may be a powerful component to the office visit (Gerber and Eiser, 2001).

Limitations to the study include small sample size, and large number of individuals unable to complete the telephone call survey. High levels of drop out in follow up surveys may result in overestimating the ease of computer use, if these individuals were less likely to provide positive attitudes about the program in follow up.

Increased resources are necessary to provide tailored information to people of different ethnicity, educational background or gender. Besides the creation of a second version of educational materials in Spanish for the Latino population, further work may still be considered to distinguish between people from Mexico, Puerto Rico, South America, or other Latin American regions. Further research is needed to better understand the cost/benefit ratio between cost of production and implementation and benefit of tailoring material to a target audience.

A New Baseline for Faculty Knowledge of Educational Technologies

Tracey Leacock, PhD
Simon Fraser University, Canada
leacock@techbc.ca

Abstract: As the pressure to use new technologies in the delivery of education increases, institutions should strive towards agreement on a new baseline level of faculty knowledge of learning technologies and an understanding of the impacts of technology on education. At TechBC, we developed a process that included an up-front investment in bringing current faculty up to the new level as well as the development of a culture that will help incoming faculty achieve the new level quickly. The key aspects of the approach include fostering a culture that encourages innovation in the use of educational technologies -- when and where they are appropriate -- and the formation of faculty into clusters for development and delivery of courseware.

In the past, there have been two extremes that described many potential users of educational technology: the technophobes and the technophiles. As the pressure to use new technologies in the delivery of education becomes ubiquitous, institutions should strive to move adherents at both extremes towards agreement on a new baseline level of knowledge for faculty and an understanding of the impacts of technology on education. At The Technical University of British Columbia (TechBC), we developed a process to do just that.

The TechBC Story

TechBC (now SFU-Surrey) uses a hybrid system (Nesbit 2002), in which face-to-face classes are mixed with online activities, to deliver degree programs in Information Technology and Interactive Arts to undergraduate and graduate learners. All courses have a significant online component delivered through our course management system (CMS), a proprietary system designed for content delivery, conferencing, etc. CMS content typically includes a combination of text, animations, links to external resources, video, interactive activities, etc. (Humphrey 2001). In the face-to-face sessions, faculty lead small group activities that enable learners to interact with and deepen their understanding of the content they are working with.

We are fortunate to have been in the position of having new programs and being able to hire faculty who have self-selected themselves as having an interest in the use of technology to improve the quality of education. However, behind the statement of interest, we have found that our faculty bring a variety of levels of technical expertise. In many cases, there has been more interest than first-hand experience.

Once we realized that not all of our faculty were comfortable with the whys (pedagogical considerations) or hows (technical considerations) of using the new technologies available to educators, we initiated an intensive and multi-faceted approach to increasing the baseline level of knowledge in these areas for all current faculty. We designed the process to become largely self-sustaining, with minimal institutional investment in across-the-board training after the initial start-up phase.

TechBC's unique situation made it easier to bring about such an approach, but the same ideas would be of great value to any institutions dealing with resistance or uncertainty around the increasingly prevalent role of technology in education.

Why Change the Baseline?

At one time, faculty could happily get by with just a pen and paper. In recent years, typing – or more appropriately, keyboarding – and even general computer literacy have become accepted basic skills.

Institutions expect that faulty will know how to send an email and how to find information on the web. The next logical step is to expect faculty to have some basic knowledge of how principles of instructional design can be applied to create solid courseware using new technologies. This knowledge must also be tied in with a good understanding of when the use of the technologies is appropriate and why.

The approach we took was designed to make this expectation explicit. By investing in "educational programs to foster these skills" (Advisory Committee for Online Learning 2001), we have changed what constitutes basic knowledge at our campus. Our goals were to improve the overall quality of courseware, increase the confidence of the faculty in working with new technologies, and establish strong working relationships between faculty and various areas of specialized support (e.g. media developers) who would be available to assist when faculty wanted to try projects that required a high level of technical expertise.

Our Approach

We used a multi-faceted approach to the initial development of the knowledge needed for this new baseline. The four main categories of effort included: faculty orientations; a mandatory course on educational technology and learning; ongoing workshops; and a formalized cluster structure for development and delivery of course materials.

Orientation. All new faculty attend an orientation session that provides an overview of what we do, how we do it, and whom to talk to about specific questions. This sets the stage in a number of ways. It clearly establishes our philosophy of teamwork – we're not sending anyone out on their own into uncharted waters. It also makes clear that we expect everyone to look for new and innovative ways that technology can *improve* learning – we aren't looking for bells and whistles, but we're not looking for the *status quo* for its own sake either. Finally, faculty have an opportunity to meet the people who can provide more advanced support, so they know what help is available. Typically, these orientations are held as group sessions just prior to the start of each term. This provides all new academic staff with a solid grounding, and allows continuing staff an opportunity to drop in to remind themselves of any services that they may not have used recently.

METL. All faculty are required to take a one-semester course called Mastering Educational Technology and Learning (METL). METL covers topics ranging from the design of measurable learning objectives, to the effective use of asynchronous conferencing, to how to integrate learning objects into online content to improve learning. This course uses the same delivery methods that faculty will use in their own classes – a combination of online resources and activities and face-to-face sessions where they can apply their new knowledge. Learners (faculty) work together in small groups, using courseware that they are currently developing or delivering as examples for discussion and activities. (See Stacey 2001 for a review.)

Ongoing workshops. TechBC also offers optional workshops on topics such as designing concept maps for content; matching learning objectives, content, and assessments; and moderating online conferences. The topics are flexible and depend on the needs of participants. These workshops may be offered by members of our Educational Technology & Learning unit or by faculty who have gained experience in particular technologies or delivery methods. The workshops are typically informal and may be as short as a brown-bag lunch or as long as a full day, depending on the needs of the topic.

Clusters. The most innovative aspect of our attempts to raise the baseline on knowledge of new technologies in education has been our use of clusters (Leacock 2001). This is also the aspect that will have the biggest impact on the self-sustainability of the process. We use clusters both for development of courseware and for delivery of courses that have many sections. Both types of clusters are formed on a term-to-term basis.

Development clusters typically consist of 4-10 developers (faculty), an instructional designer, and a project manager. Other specialists are also available as resources to the cluster on an as-needed basis (Fig. 1). The cluster is responsible for the development of a set of courses (up to 6-credits per cluster member), and the group has to follow a general pattern and timeline for development. Within these constraints, there is flexibility for different approaches. The cluster members provide ongoing feedback and insights that are directly related to each other's current development assignments.

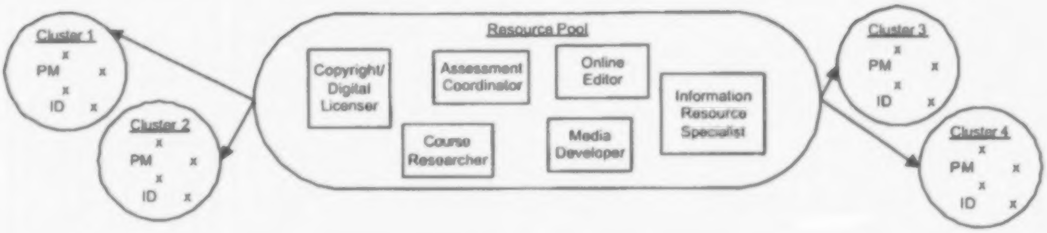

Figure 1: Structure of Development Clusters at TechBC.

Members of a cluster generally meet synchronously on a weekly basis, using a combination of face-to-face meetings and teleconferencing. They also communicate through email and informal meetings regularly. The cluster members share their experiences with using the TechBC delivery models (Course Delivery Models 2001) and available technologies in different teaching contexts. This feedback helps developers to learn from and build on what their peers have already tried, and it fosters a culture of open communication and knowledge-sharing.

Developers have a single four-month cycle in which to complete an assignment. There are three supra-cluster checkpoints: specifications review, quality circles, and the final show & tell. Each cluster may decide to implement additional internal checkpoints. At the specifications review, a university planning committee reviews the detailed plans for the courseware to ensure that they fit with the intentions of the overall programs and institutional needs. (See Module Specification System 2001.) At the quality circles checkpoint, an interdisciplinary team that includes a content expert, an instructional designer, an assessment specialist, and others reviews a sample unit of each course and provides feedback that the developer can use to improve that unit and inform the development of the remaining units (Belfer & Leacock 2002 unpublished raw data). Finally, the clusters present the completed courseware in a show & tell session that is open to all members of the university community.

The results of this cluster development process have been exciting. When we introduced this approach, many developers were new to the online environment and were not familiar with the concepts of instructional design. The feedback from within the clusters tended to be at a low level. However, after completing the METL course and going through the cluster development process once, most developers showed a marked improvement in their choice of technologies, activities, and assessments. This also meant that they were able to provide one another with better feedback as well.

We recently extended the cluster concept to the delivery of our high-enrollment courses by formally grouping all instructors of each course into clusters and encouraging them to communicate regularly on what they were doing in their sections. This helps newer instructors to learn from their more experienced peers, and it increases consistency across sections.

Outcomes

Now that we have a large percentage of experienced faculty who have achieved a new baseline level of knowledge, they automatically use that knowledge when interacting with new faculty, thus, increasing the baseline knowledge of their peers. The result is a self-sustaining culture that understands the benefits and limitations of current technologies in educational delivery and that is prepared to look for and evaluate new and innovative ways to improve education through technology and better instructional design. The tangible results include increased productivity, reduction in the overassessment of learners, strong peer-peer support networks, and more effective use of specialized support services for technically challenging projects.

BEST COPY AVAILABLE

Productivity. Prior to introducing this approach, course development tended to stretch over multiple terms, and was more likely to trickle over into delivery. Only a few courses would be developed by a few faculty in any given term. In the first semester of using this approach, we increased productivity to approximately 90 credit hours worth of courseware, developed by 19 faculty in six clusters. (Most of these faculty also held teaching responsibilities during this term.)

Assessment. At TechBC, we had identified a problem with overassessment, due to the modular nature of content delivery (courses are delivered in 5-week, 1-credit chunks, each with a transcripted grade). The quality circles and peer feedback have led to more effective ways to assess learner progress that reduce learner and faculty time commitments, while improving the validity of the assessments (Belfer 2001). The material that is developed is also more integrated across the curriculum, has better agreement between objectives, content, and assessments, and has lead to improved ratings by learners during and after delivery.

Peer Support. By changing clusters each term to meet operational needs, faculty get an opportunity to work and develop relationships with many others with similar or related interests. Faculty who studied together during METL or worked together to create courseware also tend to continue to collaborate during later development cycles and to openly discuss issues that arise during delivery.

Specialized Support. Our Educational Technology & Learning unit provides specialized support for development and delivery needs. This unit is now able to allocate its resources to new and innovative projects, as most faculty are able to take care of more basic tasks themselves.

Conclusion

At TechBC, we consciously chose to make an up-front investment in increasing faculty knowledge of the new technologies available to educators. We implemented an approach that had some mandatory components, covering basic information that applied to everyone's teaching, and some optional components that allowed those who were interested to work with certain technologies or activities more closely. The result has been as much a cultural change as a technical change. We have created an environment that encourages innovation in the search for better ways of fostering effective learning. We have created informal peer support structures that promote collaboration, rather than lone ranger or competitive approaches. Finally, we have succeeded in raising the bar on what constitutes basic knowledge of educational technologies.

Peer and Self Evaluation for Improving Student Collaboration in Online Courses

Lars Leader

Lorraine Schmertzing

Department of Curriculum & Instructional Technology
Valdosta State University
U.S.A.
lfleader@valdosta.edu

Abstract: Although student collaboration for projects offers advantages, especially in the online environment, too often student contributions to a team effort are not equitable or effective. This study addressed that problem by incorporating both peer and self-evaluation into collaborative projects undertaken by graduate students in an online course on evaluation and research methods. In one experimental group, students anonymously evaluated themselves and other team members on their collaborative efforts. Differences between this group and a control group on subsequent project grades and perceived collaboration within project teams suggested that self/peer evaluation could promote group collaboration. Survey responses indicated that after completing self/peer evaluations, students increased the frequency of communication within teams. Implications for promoting online group collaboration and further research are discussed.

Introduction

Project-based learning and the use of project work for students in general have been implemented in recent years in many schools and training organizations. Learner collaboration on the frequently complex tasks in projects is at the heart of this instructional technique. Studies provide considerable evidence that the joint problem solving in these situations is associated with better use of higher-level thinking skills, such as planning, reflection, and metacognition (O'Malley, 1995). Computer-mediated communication in distance learning has also been shown to promote critical thinking by incorporating technologies such as asynchronous discussion boards, which foster revision and reflection in the learning process (Barab, Tomas, & Merril, 2001). With the increase in instructional use of the World Wide Web, learners now often collaborate online for projects. This provides the opportunity to involve students in higher-order learning tasks while taking advantage of the practical benefits of distance education.

However, there is also a downside to student collaboration in project work. Students in collaborative groups frequently complain about some members of the group not "pulling their weight." This decrease in individual effort when performing in a group compared with working alone was termed "social loafing" by Falchikov and Goldfinch (2000). Social psychologists suggest that slacking by members of collaborative groups can be discouraged through individual accountability in the group environment (Myers, 1990). Various ways to identify the contribution of individual group members can be incorporated into assessment of project work. Yet, this is often difficult to administer, especially in an online course where it is often impossible to observe the work of the groups. Trying to identify each group member's contribution may lead to negative attitudes among students if they are asked to judge each other's contribution and make that evaluation available to the group. Or students may collude to provide inflated evaluations of each other to the instructor. The present study considers an alternative approach intended to promote better collaborative effort within project groups. The main research question in this ongoing study is, "When online project team members each anonymously evaluate the collaborative effort made by themselves and other members of their team, what are the effects of these evaluations on project quality and team member attitudes?"

Method

The students in this study took a graduate course in evaluation and research methods at a regional southeastern university. This is a required course within a totally online Instructional Technology program. Participants were graduate education students at the Masters and Educational Specialist levels. The 5 males and 23 females were nearly all of the students in two sections of the course during the years 2001 and 2002.

Among the course requirements were three major projects in which the students worked collaboratively and were assessed by a group grade on each project. The first project involved each team observing an activity, writing descriptive notes on it, and interviewing one of the participants. The team report of this qualitative fieldwork included coded excerpts, data display, and interpretation of the meaning of behaviors in the observed activity. The second project was a team evaluation of an educational or training program. This mixed-method evaluation included testing, observation, and survey. The third project was a proposal for an instructional intervention to address a concern within the evaluated program. The product for this project was a PowerPoint presentation developed by the team. The students self-selected the members of their two- or three-person teams.

For the study design, the teams were randomly assigned to two groups. During each course the primary investigator was not informed as to the assignment of particular students to the groups. Students in the intervention group ($n = 14$) anonymously evaluated themselves and their other team members after the first course project; those in the control group ($n = 14$) did not. The online evaluation form consisted of 12 statements with Likert-style responses. These statements described characteristics of a team member that would facilitate effective collaboration within the project team. One statement asked if "This teammate shared fairly in the production effort." Another statement was "This teammate communicated effectively." Another was "This teammate helped the team to effectively use the strengths of each team member." Each participant completed a separate form on each member of the team. For the self-evaluation, each participant completed a form with the same statements reworded as in this example: "I provided accurate information for the report of this project." Options for responding to each statement were: strongly agree, agree, disagree, and strongly disagree.

The dependent measures were (1) the group grades on the three projects and (2) the individual student responses to a survey completed after the first project and again after the third project. Each project was graded on points for content, format, and clarity by the primary investigator. Students worked on the second and third projects after the intervention group performed the self/peer evaluation. Therefore, the grades on these two projects were combined for analysis. The student survey consisted of 20 Likert-style questions. Some questions asked about skill in using online communication tools. An example is "What is your present level of skill using chat room discussion?" Other questions asked about the frequency of interaction using these tools, for example: "While working with your teammate(s), how often did you communicate by WebCT personal mail?" Another type of question asked about teamwork. For example, one question was "How often did problems concerning the responsibilities that members of your team were to assume affect the quality of your project?" An open-ended question at the end of each survey asked the students to comment on team project work in the course.

Both grade and survey data were analyzed using t-tests. An alpha of .05 established significance. Descriptive statistics were obtained for the survey and self/peer evaluation responses. The open-ended question responses were analyzed qualitatively for trends and themes.

Results

On the first project, the grades for the intervention group ($M = 18.29$) did not differ significantly from the grades of the control group ($M = 18.14$), indicating pre-intervention equivalence of groups. On the second and third projects, which followed the peer/self evaluation of collaboration, the grades for intervention group ($M = 41.64$) were higher than the grades of the control group ($M = 40.00$). However, this difference only approached significance, $t(1,26)$, $SE = .84$, $p = .06$.

On the first student survey no significant difference was found between the groups on their responses to any of the items, again indicating pre-intervention equivalence of groups. Responses to the second student survey, which was administered after completion of the third project, indicated significant differences on three of the 20 items. All three items asked student how often they had communicated with their teammate(s) while working on the second and third projects. Response options (and values) were: never (1), less than once per week (2), 1-2 time per week (3), 3-6 times per week (4), and daily or more frequently (5). On the item that asked about team communication by telephone, the means were 2.92 for the intervention group and 2.15 for the control group, $t(1,24)$, $SE = .36$, $p = .04$. For the item that asked about team use of a chat room, the means were 1.92 and 1.38 respectively, $t(1,26)$, $SE = .23$, $p = .03$. The third item asked about team communication by WebCT personal mail. The means were 3.61 for the intervention group and 2.69 for the control group, $t(1,26)$, $SE = .42$, $p = .04$.

Description of student survey responses for the groups combined was also obtained. When they started the course, almost half of the students were looking forward to being on a team, with the rest about equally divided between a dislike based on bad previous experiences and ambivalence over the prospect of group work. On a Likert-response scale that ranged from 1 = very uncomfortable to 4 = very comfortable, the students were, on the average, comfortable with group work in the course after the first project ($M = 3.44$) as well as after the third project ($M = 3.26$). When asked about grouping for project work, 78% on the first survey wanted to work in a group rather than individually and 72% on the second survey preferred group work. The students responded that for their own learning the team project work was effective ($M = 3.27$ on the first survey and 3.42 on the second one), with a four-point scale from very ineffective to very effective.

A general analysis of the qualitative data from the open-ended survey questions revealed several major themes. One of the prominent ones focused on the benefit of having someone to use as a "sounding board". It is interesting to note that this theme appeared much more regularly in the comments block of the early survey than the later survey. Students identified a variety of ways that having the "sounding board" was beneficial, such as: "I like having someone I can bounce my ideas off of," "Working in my team has been conducive to brainstorming, has provided different viewpoints leading to better ideas, and it has helped us to begin to grasp complex concepts by talking them out," and "Getting another person's input has helped me to see some other dimensions that I would not have picked up on alone."

Another recurring theme was related to individuals and how their own traits either helped or hindered the team experiences. Routine comments regarding team members like, "when all members pull their weight, group work could be effective," "[often] you end up with one or two people doing most of the work (if not all)," and "If all partners contribute to the work load, the learning experience can be invaluable" were present. However, there were also a number of students who chose to emphasize the importance of each person's involvement in a more positive manner: "I work well with a team when I have the freedom to work with whomever I choose [which was the case in this project]," "both of us seem to compliment each other," "the grouping was great," and "grouping should be done carefully." Students chose to make the point somewhat differently, but either in the early survey or the late survey most students either blatantly stated or eluded to the idea that the success of teamwork lies in the natural ability of the team to "fit" together. We chose to include the word, "natural" ability because there was only one comment that indicated a process of working to create a team fit. Other than the admission that, "at times coordination was a bit confusing (due to my work schedule) though successful due to my partner's coordinating and communication skills," no other student indicated a shift from a difficult working relationship to a beneficial team relationship.

Based on a curiosity about how the intervention might change the descriptive language students used in their comments on teamwork, a simple analysis was done to compare the responses from the intervention and control groups. Each comment was examined for words or phrases that may demonstrate strong emotion and/or a more personal tone in the context of the sentence. Some of the key words were friend, feel, personally, excuses, unhappy, stressful, joy, nice, and fear. It did not appear that the intervention changed the descriptive language. Rather it was fairly consistent that students who used emotional language on the early survey were the same students who used it on the later survey and it did not matter whether they were in the control group or the intervention group.

Discussion

The focus of this study was on how peer and self-evaluation for collaborative effort in online project teams might affect project quality and team member attitudes. For project quality, the results indicate that the effect was borderline. Grades for the intervention group on the projects which they undertook and completed after their peer and self-evaluation only approached being significantly higher than the grades of the students in the control group. On the evaluation forms the students responded to statements that were meant to serve as criteria for effective collaboration. Responding to these rating criteria was anticipated to have beneficial effects on team members. The self-evaluation was expected to promote personal development and improve interaction among team members. It was also meant to compel team members to direct their individual efforts in ways they otherwise might have ignored or omitted. Similarly, the peer evaluation was expected to provide direction for improving group collaboration. As explained by Haas and Hass (1998), reflecting on the various criteria that make for an effective collaborative effort and evaluating how other members of the team measure up may suggest to the student evaluator opportunities for improving the group effort.

However, the only measures that did differ significantly between the intervention and control groups were student responses on three of the student survey items. Each of the three items concerned the frequency of interaction between students when using communication tools. Students in the intervention group reported that they communicated with others on their teams significantly more frequently by telephone, chat room, and e-mail than did the students in the control group. This finding appears to indicate that the self/peer evaluation promoted more communication within teams. It may be that students' awareness of the importance of communicating frequently with others on the team was positively influenced by the rating criteria on the evaluation forms. Two of the evaluation items focusing specifically on communication within the team were "This teammate met (in-person or online) when needed" and "This teammate communicated effectively." The thought occurs to us that this increase in frequency is one of the easier changes to realize for improving collaboration. As our analysis of the open-ended comments suggested, students in neither the intervention group nor the control group indicated that the quality of their collaboration improved in such areas as fair distribution of effort, suggesting ideas and accepting others' ideas, and effectively using the strengths of each team member. Inculcation of these characteristics of superior collaboration may require more direct methods, such as training focused on effective collaboration.

This research is an on-going effort. We plan to continue the study with additional participants in the current and future sections of the evaluation and research methods course. With data obtained from more participants, the effectiveness of using peer and self-evaluation to promote online collaboration in student teams should become clearer.

Academic Administration and Organization Model of Digital Distance Universities

In-Sook Lee, Sejong University, 98 Gunja-dong, Gwangjin-gu
Seoul, Korea, inlee@sejong.ac.kr

Abstract: Digital distance education system has become a growing form at the higher education sector. This study suggests a model of academic administration and organization for digital distance universities, which would serve as a corner stone for early successful establishment and enhancement of educational quality. This model shows that distance universities should be equipped with services in both the faculty and staff sides of academic administration, instruction-learning support, student support and welfare, and educational evaluation and these services also need support in the form of organization. The model also emphasizes flexibility and dynamism that connects services and organizations and enables timely provision of services and top-level receptiveness.

Introduction

Digital distance education system has become a growing form at the higher education sector. In Korea, the Ministry of Education and Human Resources permits the establishment of digital distance universities, as part of lifelong education initiatives, and further tries to extend the scope of those universities. The governmental supports have accelerated distance education systems in terms of quantity: Now it is a high time for more attention to be paid to 'quality'. It definitely needs to study a framework of academic and organizational systems that can embrace the diverse needs of learners, the pedagogical considerations of various technologies, and the various instructional services.

The purpose of this study is to suggest a model of academic administration and organization for digital distance universities, which would serve as a corner stone for early successful establishment and enhancement of educational quality. This study was accomplished through the following methods: Content analysis of related documents through which a theoretical framework for the model has been derived. Surveys on three different types of research subjects, which include 15 national and 4 international digital distance universities, 2 national distance education companies, and 18 experts.

Results and Suggestions

Eight Propositions

Based on the reflections on all results of literature review, surveys, and benchmarking, the following eight propositions were suggested that the academic and organizational model of digital distance universities has meant to satisfy:
1) Strategic goals driving digital distance education can vary and organizational structures, governance, programmatic emphases, and financial models should be compatible with the strategic goals. 2) To be successful and competitive, digital distance education will require a governance model with a level of dynamism and flexibility dramatically different from the traditional faculty governance model. 3) Organizational governance should create right mixes about the responsibilities and agreeing on who make what decisions. 4) Governance and organizational structures for attracting and retaining qualified teaching faculty and instructional support personnel are emphasized. 5) Providing appropriate academic and student services to learners is a critical quality issue. 6) With distance education, partnerships are essential. 7) A multitude of policy issues associated with digital distance education exists - ownership of intellectual

property, workload, accessibility, appropriate use, conflict of interest, to name a few. 8) Digital distance education can be an expensive proposition so that only institutions with significant investment capacity should establish distance education.

Suggested Academic Administration and Organization Model

On the basis of above eight propositions, we propose an academic administration and organization model for successful educational service (Figure 1).

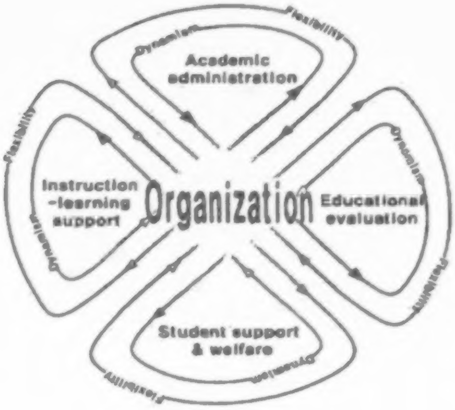

Figure 1. Academic administration and organization model

This model shows that distance universities should be equipped with services in both the faculty and staff sides of academic administration, instruction-learning support, student support and welfare, and educational evaluation and these services also need support in the form of organization. The model also emphasizes flexibility and dynamism that connects services and organizations and enables timely provision of services and top-level receptiveness.

Academic administration covers the ideas of academic term system, curriculum operation model, academic organization, tuition and fee, admission and registration, learning quality control, and enrollment size. Instruction-learning support deals with the issues of curriculum quality control, content quality control, instruction-learning process quality control, appropriate technology infrastructure, and faculty support system. Student support and welfare deals with the issues of academic information, learning support service, requests and complaints handling, and technology infrastructure. Educational evaluation introduces various key ideas for quality control in distance education. Teaching and administration support organization suggests that instructional support, system management, marketing and public relations are given more emphasis in distance universities than in traditional offline universities. Organizational structure exhibits more diversity in institutions that provide services in partnerships than in institutions that provide all services by themselves.

A variety of support organizations are needed in distance universities for quality control of various aspects of the institutions including the following (Figure 2): (1) curriculum development and assessment (curriculum development, quality control in curriculum, assessment of education effectiveness); (2) contents development (instructional design, graphic design, web programming, multimedia development); (3) student support (academic information, learning evaluation system, evaluation system for learning process, learning progress checking, etc.); (4) faculty support for instructional development (instructor training, consulting, instructional resource development); (5) marketing and promotion (student recruiting,

Delphi Study on Competency Model of Online Instructor

Online instruction has greatly changed the learning environment and learning process in comparison with traditional instruction. It requires a new kind of roles and competencies in instructors (Oh, 1998; Berge, 1996; Kearsley et al., 1995; Kearsley, 200; Reeve & Reeve, 1997). Nonetheless, many studies have been made on technology related to online education and its potential, whereas few studies have been conducted to identify what instructors actually do online (Salmon, 2000). Therefore, there is a need for a systematic and comprehensive study of online instructer's roles and competencies.

This study attempted to provide one indicator for training, selection and placement of future online instructors by identifying online instructor's roles and competencies in a more systematic and comprehensive way. To attain this goal, the following research questions were set:

First, what major roles and competences are required of online instructors?

Second, what role cluster by each role is required of online instructors?

Third, what is the descriptive competency model synthesizing online instructors' roles and competencies?

To fulfill these study questions, the current study conducted the questionnaire research three times with the use of the Delphi technique, especially the Modified Delphi technique which is a research method of finding out the consensus by extracting and synthesizing an expert group's opinions and judgement.

Based on the study results, the following conclusion was drawn:

First, the major role and competency required of online instructors were as follows: 6 major roles required of online instructors include 'interaction facilitator and manager', 'information manager and user', 'classroom evaluator', 'collaborator', 'subject matter expert', and 'planner'. The items rated as the core competency of online instructors totalled 15 items, of which 5 items were found to be 'subject matter expertise', 'interaction facilitation and management', 'instructional design', 'online communication', and 'learning activity evaluation'.

Second, 18 competencies were adopted as the competency cluster of the 'interaction facilitator/manager'. 21 competencies were adopted as the competency cluster of the 'information manager/user'. 14 competencies were adopted as the competency cluster of 'classroom evaluator'. 19 competencies were adopted as the competency cluster of 'collaborator'. 16 competencies were adopted as the competency cluster of 'subject matter expert'. And 16 competencies were adopted as 'planner'.

Third, 5 finally identified core competencies included 'subject matter expert', 'interaction facilitation and management', 'instructional design', 'online communication', and 'learning activity evaluation'. Basic common competency is what becomes commonly fundamental in performing every role adopted in this research. It was found that 7 finally identified basic common competencies. And 'role-related competency' is the competency necessary in carrying out a particular role and refers to the competency partially applied according to 6 roles. It was found that the 'role-related competency' of the online instructor accounted for 14 competencies.

Time and Resource Issues Pertaining to the Design and the Management of Course Materials for a WebCT-Based Project with Engineering Students

Geneviève Légaré
Concordia University, Montréal, Canada
legare@vax2.concordia.ca

Abstract

This paper describes a project using WebCT with engineering students registered in the course "Impacts of Technology on Society" at Concordia University, Montréal. Students carried out five individual assignments that were posted and returned using WebCT. The assignments were used to provide practice in writing as well as to develop critical thinking skills. More specifically, WebCT was used primarily as a mode of delivery to post and to receive student assignments. While a content analysis study was subsequently conducted to analyze the incidence of critical thinking skills in student assignments, the purpose here is to address some of the practical aspects of using WebCT. Thus, the focus of the paper is on the issues of time and resources required to carry out instructional activities using WebCT.

Introduction

Background

The course "Impacts of Technology on Society" is a required course for all fourth year engineering students registered at Concordia University. The course is specifically designed to address social, environmental, ethical, and political issues pertaining to the role of technology in society. Typically, the assignments consist of two short papers (5-7 pages), one major report carried out in teams and a class presentation. Instructional approaches include class discussions, lectures and case presentations. Eighty-five students registered in two sections of the course participated in this project.

One of the challenge with teaching the course is that the students come in with very little experience in writing and expressing ideas. To address this issue, the instructors decided to use WebCT primarily as a mode of communication, which allowed for more writing practices. In the revised version of the course, the short papers were replaced with five written assignments, that is, two essays and three case studies of increasing difficulty. The WebCT assignments were designed and managed by the teaching assistant/researcher, while all other activities were handled by the course instructor.

WebCT Features

From an instructional point of view, WebCT offers a number of interesting features. One can present on-line course materials (documents, lectures notes, course outlines, exercises etc.); provide glossaries for specific terms and concepts; develop quizzes and surveys; communicate by e-mail and create discussion groups; manage student files (for example, to post grades or to track their on-line visits). Course materials can be created as a multimedia package which may include, in addition to the usual text, images such as photographs or graphics, sound and video excerpts, and links to external websites. In addition, design features such as limiting access, determining availibility date and other control features are also available. One of the main advantage of WebCT is that the course content is restricted to the students registered in the course and available at the user's convenience. In short, WebCT presents a series of

BEST COPY AVAILABLE

advantages for the instructor who wishes to go beyond the traditional lecture approach and develop richer and more complex course materials.

Given our needs and our means, we used WebCT primarily as a communication device rather than as a fully developed interactive tool. Consequently, we used the interface mainly to introduce course materials, to communicate to students by e-mail and to post grades. We also used the quizz feature to collect student's feedback about the instructional approaches. For the purpose of this presentation however, only the issues pertaining to the posting of course materials will be addressed.

Characteristics of the Course Materials

The assignments were two essays and three case studies pertaining to the issue of food production technologies. The case studies were specifically designed for the course, using Leenders and Erskine's model of case writing (1989). The documents were quite complex and voluminous, ranging from seven to 20 pages. We designed the case studies in the typical constructivist fashion (see, for example, Cognition and Technology Group at Vanderbilt, 1990; Lave & Wenger, 1991). Multiple perspectives were provided to the students using different visual media. Thus, all information necessary to identify problems and to make recommendations was provided either as articles, links to relevant websites, graphics, images and statistics. Students had to sift through the information, identify the problem (s) and offer possible solution (s). All course materials were created using Claris HomePage and then were saved as a "zip" file.

Time and Resources Issues

While the integration of communication and information technologies such as WebCT in a course offers a great instructional potential, one should not neglect the time involved in creating and managing the materials and additional resources required to use such means in an efficient and effective manner. These issues are discussed below.

Time Issues

While designing materials for instructional technologies may require more time than regular print-based material, using WebCT entails that more "person-time" will be required to deal with logistics issues such as uploading and testing the materials and managing students' files. Thus, four general steps may be considered: 1) Designing the materials; 2) Preparing the material for the WebCT environment; 3) Organizing the logistics involved in using WebCT and 4) Conducting the instructional activities per se.

1) Designing the Materials for a WebCT Environment

The time spent on this step depends more on the type of document to be prepared for the course than the use of a communication technology such as WebCT. Traditional print-based materials such as lecture notes for example, will require less designing time than a case study or a Web page that introduces images, graphics and links. In WebCT, the usual steps involved in the design of interactive materials have to be covered: searching for content, organizing the information in a meaningful way for the learners, validating the content with subject-matter experts and conducting a formative evaluation. In other words, creating an interactive document that includes several media involves more design time than print-based materials. However, the instructor who wants to use WebCT in an interactive fashion will have to learn how to use a web page design software.

2) Preparing for the WebCT Environment

After the material has been created, one has to upload the course materials in WebCT. First, the instructor needs to become familiar with the designer's view options of the shell. In other words, the instructor has to understand the logic behind the design of the WebCT shell. This logic is not totally intuitive. For example, the zipped materials first have to be uploaded in the management tree, then unzipped in the desired folder. All images and links have to be verified to make sure that they have been uploaded and then successfully unzipped. Then one has to verify that all the links work. The next step is to give the students access to the document. This means that while the material may have been uploaded in WebCT, the document is still not accessible by the students. Toggling from the designer's view to the student view is probably the most time-consuming step since one has to go out entirely from the browser and then enter as a student to verify that all the links and the images really appear.

In short, the steps involved in uploading the materials include zipping and unzipping the file, verifying that all the images have been uploaded, organizing the files in the management tree, verifying that the file does appear in the student mode, setting up the access for students and finally, testing the document in student mode. In our project, uploading the course materials and testing the set up required an average of three hours for each assignment. Finally, in the 3.11 version, it was not possible to upload the same material for two sections at once. In other words, when one teaches two sections of the same course, the uploading procedures have to be repeated twice. It is not possible to "duplicate" or to dispatch the materials and the set up to a running course.

3) Organizing the Logistics

Organizing the logistics surrounding the use of WebCT is another issue worth considering before using WebCT. One has to ensure that everybody has access to a computer either from home or from a lab and that all students create their account by a given date. One also has to do some trouble shooting and updating with the students who are experiencing difficulties. Yet, the most time-consuming task in terms of using WebCT in the classoorm is the management of students's assignments. In this project, the teaching assistant/researcher had to : 1) open up the e-mail messages and the attachments; 2) verify the format and the filename; 3) return a reception notice; 4) file the assignment in the proper folder and; 5) assign a participation grade to the student. Although the WebCT part of the course was also designed for research purposes (i.-e. an increased number of assignments) creating and receiving even a lesser number of assignments in WebCT would still require quite some time. To illustrate the point, the task of managing student assignments, despite the application of systematic procedures, required 1.5 days of work per assignment for 85 students.

4) Conducting the Instructional Activities

The use of WebCT does not directly affect the amount of time dedicated to the instructional task per se. In other words, the grading and the provision of feedback is as time-consuming in a WebCT environment as it is in traditional approaches. However, one observation about our experience is that we had the feeling of spending too much time on the logistics and the management of the student files and not enough on the instructional tasks themselves.

Resource Issues

Technical Support for Students

In order to facilitate the students' use of WebCT it is essential to offer proper technical support, especially if it is their first experience with such an environment. In our case, a handout outlining the steps about how to log on to the system was distributed in class. A help line was also made available for the students, as well as a drop-in session for trouble-shooting. In addition, a class presentation of the environment was presented at the beginning of the term.

Clear instructions are essential for submitting electronic files. Such instructions should contain information as to how to give a filename (using the student's last name of the student and their first initials as well as the assignment number); what type of document is accepted (e.g. Word, Word Perfect, PDF, etc.); an explanation about the meaning of the extension (e.g. ".doc", ".pdf"). At first, we perceived this information as being trivial, but we were surprised to find out that quite a few students had little knowledge about the type or the version of word processing software.

Technical Support for Instructors

Learning to navigate in WebCT is not as intuitive as it could be. Some time and energy have to be invested prior to designing the course materials or the course interface. Instructors, teaching assistant and facilitators have to be supported in order to develop the course. In our experience, we were a team of five people. The head instructor with the help of the Information and Instructional Technology Service staff, created the interface for the course and chose the icons and the features to be used; the teaching-assistant/researcher created the materials to be uploaded, debugged and organized the set-up, as well as managed the students' assignments; and finally, two instructors managed the mail and the student grades to be posted. In essence, the instructors, in order to be successful and efficient with WebCT, need some form of technical support from the university, as well as some teaching assistance resources dedicated to the magement of the course in WebCT.

Conclusion

In conclusion, the use of complex and voluminous case studies containing graphics, images, texts, references, and links to relevant websites was facilitated by the WebCT environment. However, as our experience demonstrated, more person-time was dedicated to the design, the logistics, and the management of student assignments than on the instructional activities per se. This implies that whenever planning to use WebCT, one has to expect that more time will be spent on non-instructional task. Consequently, when planning to use an interface such as WebCT, careful planning of physical and human resources has to be considered in order to ensure a successful and relevant integration of WebCT in a course.

Teaching about Mythic Kings: How Integrating Multi-Media Presentation Technology with Traditional Essay Writing Has Helped Students Learn More History

Abstract of Brief Paper Proposal for the Association for the Advancement of Computing in Education, World Conference, October 15-19, 2002, Montreal, Canada

By David Walter Leinweber, Ph.D.
Associate Professor of History
Oxford College of Emory University

OVERVIEW OF THE PROPOSAL

This brief paper highlights experiences and issues related to incorporating multi—media technology into a special topics course I am teaching this Spring Semester at Oxford College of Emory University – *HST 385: Mythic Kings*. A major feature of the course is the preparation of a multi-media presentation prepared by students, based on a significant historical essay they have written. I have found this fusion of traditional essay writing with modern multi-media technological capacities to add an exciting and enriching dimension to students' learning about history.

In a brief presentation to the World Association for the Advancement of Computing in Education, I would like to share some of my experiences using multi-media technology with *HST 385:Mythic Kings*, including some illustrations/examples taken from students' work. I would also like to share some of the practical and philosophical issues I addressed as I configured technology into this course in a very central way.

Having each student convert major written essays into major multi-media presentations has helped them integrate art, music, architecture, and literature into a larger historical framework. The result is a much deeper level of learning that shows students how disparate peoples, places, and periods relate to each other. In addition, technology has helped students directly see how such considerations as music and art are important parts of history, not discrete entities to be considered only by artists, musicians, or art and music historians.

BACKGROUND REGARDING THE COURSE

HST 385: Mythic Kings is a special topics class designed for a rather small group of students who have completed the pre-requisite of *HST 101: Western Civilization Through the Reformation*. There are seven students in this course, all very well-prepared for the discussion, special projects, and research that the course requires. This is important, as it allows us to assume some general familiarity with the various periods discussed, as well as a certain seriousness one brings to the topic.

Also, *HST 385: Mythic Kings* was designed and supported based upon work done by the instructor while a 2001 participant in The Teaching, Learning, and Technology Institute (TLTI), sponsored by Oxford College of Emory University. TLTI expert instruction was directly designed around the proposed course syllabus. The expert support of Oxford's technological staff was a critical element of this course, both as I developed it, and as students proceeded towards completing it.

Other key elements of the *HST 385: Mythic Kings* syllabus are itemized below.

INDIVIDUALIZED SYLLABI

In addition to mundane matters of course administration, the syllabus for HST 385 provided a list of particular "mythic kings." Among these were included Osiris, David, Priam, Theseus, Alexander the Great, Arthur, Charlemagne, and Napoleon. Each student selected his or her own Mythic King from this list, and was provided with an extensive list of references for that particular figure. These references included major primary sources on the historical figure in question, as well as literary, artistic, and musical works that reflected the monarch's enduring legacy in culture and myth. Below you will find a sample of the syllabus references given for one of the student's projects, Theseus as a Mythic King.

A. Theseus

Literature: Boccaccio, Giovanni, *Teseida;* Chaucer, Geoffrey, "The Knight's Tale" in *Canterbury Tales;* Dante, *The Inferno*, Canto XII; Euripides, *Hippolytus;* Hawthorne, Nathaniel, "The Minotaur," in *Tanglewood Tales;* Ovid, *Metamorphoses Book VIII;* Plutarch, *Theseus;* Seneca, *Phaedra;* Shakespeare, William, *A Midsummer Night's Dream; – Two Noble Kinsmen*

Music: Richard Strauss, *Ariadne on Naxos* (1912); Milhaud, Darius, *L'Abandon d'Ariane* (1928); *--La Déliverance de Thésée* (1928); Britten, Benjamin, *A Midsummer Night's Dream* (1960); Mendelssohn, Felix, *A Midsummer Night's Dream* (1876); Roussel, Albert, *Bacchus et Ariane* (1930).

Note that an important component of the course was the inclusion of much classical music – operas, oratorios, piano concertos, symphonies, and ballets. Several students chafed some at this. But they are learning to see music (and art) as not just something for people in music departments, but as an important part of the historical record. I viewed the inclusion of music in the syllabus as essential, and have remained firm that students consult the various works related to their particular topics. Music was an important part of the course in the basic sense; but it also presents one of the most exciting potentials for the multi-media component of the course.

TRADITIONAL RESEARCH AND ESSAY WRITING

The central feature of the syllabus was that each student would prepare a major and quite traditional research essay of 15-20 pages in length. Due on the last day of class, the essay focuses on the historical and cultural legacy of a particular mythic king. These are footnoted papers, with bibliographies.

Before completing this major essay, students would write a series of short papers in preparation. Assigned topics for these shorter papers were: The Historical King (e.g. Arthur); Sources of Knowledge about the Historical King; The Image of the King in the Arts; The Kingly Ideal.

Having completed these very serious and meticulous papers, students can generally speak with true authority on their particular king. They are therefore grounded in a serious body of content knowledge that they can then import into their Multi-Media presentations. This grounding in a rather traditional approach to history is very important, and adds enormously to the exciting and creative work they can then incorporate into the technology component of the course.

MULTI-MEDIA PRESENTATION

The essay completed by students is converted into a major multi-media presentation that summarizes its major points, and illustrates them with a wide variety of materials, including maps, music, art, and key passages from literature. This conversion of the written essay into a very carefully structured and thoughtfully conceived multi-media presentation is a critical component of the *HST 385:Mythic Kings* course. The presentations are scheduled for 45 minutes each, so they constitute a major segment of the student's work for the semester.

As a critical sub-component of the Mythic Kings multi-media presentations, students select appropriate and relevant music clips from a variety of musical sources. They integrate the music into the larger framework of important themes and images drawn from the life and times of their particular king. Slides featuring art, architecture, portraits, and other relevant images are organized thematically into sub-presentations that highlight the relationship between history and the Fine Arts

This key musical aspect of the Mythic Kings course has helped students relate such "musical" figures as Palestrina, Purcell, Handel, Berlioz, or Britten, to the larger historical context of their times. It has highlighted for them, and me, how a Handel Oratorio from the eighteenth century can relate to Renaissance Art, which can also relate to famous literary passages from Ovid, or Vergil, or the Bible, or great buildings of the world. The use of PowerPoint technology has illustrated this for them in powerful ways that I could not have imagined even seven or eight years ago.

CONCLUSION

As a rather traditional history teacher, I am very pleased that technology has provided an enormously enriching dimension to my special topics course. Technology has not conflicted with the content of the course. It has not replaced solid learning with bells and whistles. Multi-media technology, coupled with the completion of a serious traditional essay, has enabled my students to gain a much broader sense of how common figures, stories, images, and themes can connect disparate peoples, places, and periods. This has made a very significance difference in my class.

In my presentation to the World Conference for the Association for the Advancement of Computing in Education, I would like to share some of my experiences with using multimedia technology in *HST 385: Mythic Kings* at Oxford College of Emory University.

Reusable Learning Objects: Hazards, Hi-Performance, and a New Convergence

Juan Leon, Ph.D.
Vice-President, Learning and Knowledge Management Strategies
Intelli-media
U.S.A.
juanleon@comcast.net

Abstract: This paper addresses the growing gap between the promise of Reusable Learning Object (RLO) based content development and the sometimes disappointing reality of RLO performance in deployment. After reviewing the principal causes of these disappointments, the discussion outlines strategies for maximizing the benefits of RLO approaches. The first strategy applies most to Instructional Design processes. It demands special attention to curriculum driven training development. The second strategy applies most to Knowledge Management techniques. It demands a sophisticated understanding of metadata schemes and rule-based automation. The discussion concludes by reviewing the social forces and industry trends that are driving the evolution of RLO based systems. Of these, the increasing use of competency-based models of organizational development is seen as the trend most likely to complement RLO based approaches to content creation and management.

The past year was in some ways a good one for realizing return on investment (ROI) with e-Learning. e-Learning delivered new product information to sales forces in the field, reducing their time out of action. For other geographically dispersed employees, classes and discussions normally held at a central site were held over the Web. Collapsing distance in these ways, e-Learning's web-based mode of delivery trimmed training travel budgets across numerous industries.

Not uncommonly, the e-Learning windfall is being reinvested by training departments through the purchase of Learning Management Systems (LMSs) or Learning and Content Management Systems (LCMSs). Will these major investments produce comparably outstanding results by way of the course and content management they offer? The answer may depend in part on how successfully these systems can be stocked with high-quality, standards based course materials. Without the content, the systems will be no more than administrative tools, a great convenience at course registration time, but of no direct consequence to training itself. Without the standardization, these systems will deliver little by way of useful content capture and reuse.

With regard to both these issues, the most promising and problematic feature of the new LMSs and, especially, the LCMSs, is the "Reusable Learning Object" (RLO). "Create once, use many" has been an--admittedly awkward--RLO tagline throughout their evolution. The tagline expresses the idea that instruction can be systematically decomposed into small units and then stored in accordance with internationally agreed upon standards for "packaging". Appropriately labeled, this unit of instruction can function as a piece of "LEGO" in an open and growing world of such LEGO pieces. Each piece is ready to be combined and recombined with others to suit multiple training and information exchange purposes.

Thus, the RLO approach to content creation and management can promise several things, among them:

- Personalized learning
- Collaborative authoring
- Easily modified content libraries
- Efficient management of instructional assets (typically achieved by housing them in a database of RLOs)

Designed to be modular, sharable, and reusable, RLOs are conceived as the basic units of a component based learning (and knowledge management) strategy that can produce remarkably high returns on investment.

Inherent Difficulties

However, RLO based training development systems have often proven difficult to implement. "A great idea, but it doesn't work in reality", has too often become the RLO adopter's refrain. What tends to give rise to this kind of disappointment? The following are frequently unanticipated yet all-too-common difficulties:

- RLO based development brings with it technical challenges that are not only more daunting than those posed by e-Learning or other forms of technology based training but are *different in kind*.
- RLO based development requires more planning up front than training departments are accustomed to or may have the time for.
- Instructional designers don't like RLO based approaches, or remain dubious of their benefits.

There are also larger organizational hurdles. In many organizations content functions and training functions are widely fragmented across business units; and there is not enough understanding of what standards based development involves. These organizational issues must be addressed before real economies of scale can be seen in RLO based content development and content management.

Where to Begin for Training Departments

Responding to these new technical and organizational challenges will require greater levels of cooperation among training departments and IT or IS groups. Training departments will increasingly need to think of the IT or IS group not as a source of "support" alone, but as a partner in enterprise-wide communications, education, and knowledge management efforts. While developing these enhanced intra-organizational relationships, the training department will have to contend with challenges proper to training development itself. The greatest of these is the challenge of achieving coherence in RLO based course construction.

Coherence is that subjective experience that is created by a course composed of well-integrated parts. This sense of coherence is fundamental to understanding and learning. We experience coherence when a course maintains:

- subject matter consistency and natural progression
- logical consistency and natural progression
- thematic consistency and natural progression
- aesthetic wholeness (including consistency of style)

Because RLOs are designed to function as stand-alone units independent of any context, when linked together into courses they tend to produce discontinuities in subject matter, in logic, in theme, and in the "look and feel" of course components. Consequently, course coherence is not likely to be the result of a hastily conceived RLO based development strategy.

An Effective Approach

The answer to this particular challenge is not to create RLOs according to a pre-defined formula—that would defeat their special purpose—but to design them within the framework of a well-planned curriculum, one that incorporates standards compliant classification schemes allowing for consistent labeling of RLOs and efficient retrieval of the RLOs from databases. The curriculum must also be specified in detail sufficient to allow each RLO to target its own clearly focused learning objective.

Wyeth Pharmaceutical's successful implementation of an enterprise learning and content management system last year took a still more radical approach that is instructive. Before building a new curriculum they stepped back and built up a competency model. Their motto: "Design your curriculum in light of your competency model." Doing so helped turn training development into an efficient, enterprise-wide process, moving it away from the purely project driven model of production that had resulted in a "jigsaw puzzle" of training materials created ad hoc. (See Dr. Roshan's paper on e-Learning at Wyeth for more on that organization's integrated approach to training, knowledge management, and organizational development.)

Working toward related goals, Pfizer's training groups have championed efforts to collaborate with Human Resources in developing an enterprise-wide capabilities model. The model supports curricula that are both more comprehensive than in the past and more attuned to the needs of the individual learner. Particularly noteworthy, Pfizer's capabilities model and new curricula support training follow-up and career-long professional development.

Another Effective Approach

The challenge of RLO based course coherence can be further addressed through the use of RLO authoring and management tools that aid in the creation and maintenance of coherence. These tools do so, in part, by enforcing classification schemes, conducting intelligent searches against RLO databases, guiding course designers in the final selection of course components, and helping in the real-time authoring of transitional material unique to a particular course under construction. They help turn instructional design expertise into useful "rules" that can be applied semi-automatically.

Finally, instructional designers may need to learn to think and work in new ways, producing more compact and carefully structured units of instruction while keeping a close eye on curricular objectives.

Consequential Convergences

Producing high-quality RLO based content may be difficult, but the challenge is not likely to be withdrawn anytime soon. Today's explorations of training development based on RLO models comes as a natural consequence of five on-going social and industry trends:

- E-Learning is becoming a commonly used tool, one essential to the smooth operations of critical business processes. Findings from a recent survey of training professionals indicate that over 45% of the organizations polled now use e-Learning as an essential part of their business operations (SRI, 2002).
- "Blended" learning is being increasingly favored. (Driscoll, 2002)
- Both training content and performance support resources are being integrated with organizational IS and Knowledge Management efforts.
- Standards for content packaging and uniform labeling conventions are being widely adopted. It is now difficult to find a serious developer of e-Learning related tools or content that does not comply (to some degree) with AICC, SCORM and / or IMS standards and specifications for interoperability.
- Intranets and the Internet are increasingly taken for granted as communications channels, as are the consistency in technical formats and standards they provide.

When it comes to the growth of RLO based training development, these five trends will continue to provide the push, the pull, or both. Some of the reasons for this include the following:

- Materials digitized for e-Learning are ready to be placed into Learning Objects, and e-Learning now housed in databases—instead of books and binders—is only a small conceptual distance away from RLO course components housed in databases.
- Blended approaches require training materials that can be rapidly used in smaller chunks and quickly customized, while corporate CIOs are more alert than ever to the possibility of capturing and exploiting the knowledge produced by training departments.
- As the corporate world moves toward standards-based content development and exchange, no one will want to be left out or stigmatized as "incompatible".
- The continued evolution of ubiquitous computing will only increase demand for the kind of just-in-time training and information that are the forte of RLO based systems.

Despite the challenges inherent to RLO based content development, then, it is very likely that the training industry will continue to move in the RLO direction. While caution and even skepticism are warranted, we may expect that RLOs, in some form, are soon likely to begin populating efficient learning and content management systems. Experience with RLO implementations may lead to greater successes as we increasingly fulfill the promises of well-made, well-managed and well-used digital content libraries. In particular, the on-going development of competency and capabilities training models will better support the design of the comprehensive curricula essential to practical success with large-scale RLO implementations.

Looking to the horizon, how might the convergence of RLOs and competency model trends further evolve?

Standards and specifications bodies such as the IEEE Learning Technology Standards Committee (LTSC), the IMS Global Learning Consortium (IMS), and others will need to develop the taxonomies through which competencies will be defined and mapped in and across competency management systems. This will be a far more difficult task than that of specifying an RLO package's structure or the metadata to be used in RLO tagging.

Note, for instance, the complexity—and breadth—of any reasonable working definition of "competency", this one crafted by the HR-XML Competency Workgroup last year:

> A specific, identifiable, definable, and measurable knowledge, skill, ability and/or other deployment-related characteristic (e.g. attitude, behavior, physical ability) which a human resource may possess and which is necessary for, or material to, the performance of an activity within a specific business context. (Bork & Kiel, 2001)

Rather than agreeing upon packaging conventions and the kind of classification information that is important to know about a Learning Object, creating complete taxonomies of workplace competencies would involve defining and mapping *all relevant human actions and attitudes as they pertain to carrying out a given task in a given sphere of business activity*. Little wonder, then, that competency specifications and standards groups are having trouble pursuing their goals and that the HR-XML Competency Workgroup makes a point of rejecting taxonomy building altogether.

Instead, it takes on the more manageable burden of creating an XML Schema that provides practical means to exchange information about competencies in a variety of business contexts. The Schema allows competencies to be defined one at a time, a step-by-step approach thay may allow for the piece-by-piece creation of comprehensive, coherent RLO libraries available in the future workplace.

Abstract: Electronic communication has become an integral part of higher education. Along with the growth of electronic communication is the rise of Web-based courses. This empirical study surveyed 128 students enrolled in 29 courses offered entirely over the Internet to determine the dimensions which underlie student satisfaction with Web-based courses and examined how these dimensions can be used to predict student satisfaction levels. This study also examined the relationship between demographic variables, such as gender, year in school, students' prior computer, email, and Internet proficiency, as well as, Web-based course experience and their satisfaction levels with Web-based courses. The implication of this study is that instructors of Web-based courses may be able to increase their online students' satisfaction by addressing the appropriate factors underlying student satisfaction.

Introduction

The Internet has impacted the way we learn. More and more courses offered by institutions of higher education are delivered via the Internet. A recent survey by the U.S. Department of Education's National Center for Education Statistics (NCES) found Web-based distance education to be the most widespread mode of delivery (Lewis, et. al, 1999). At least 58 percent of institutions which offered distance education used Web-based courses, compared to 54 percent that used two-way interactive video and 47 percent which used one-way pre-recorded video. Because Web-based distance education is a fast-growing area, it is imperative that we gain a better understanding of this mode of distance education delivery. Most of the current literature about Web-based learning is based upon anecdotal experience or qualitative study (Kearsley, 1998). Many researchers agree that one of the greatest problems with online learning is the lack of empirical research and quantitative studies (McIssac & Gunawardena, 1996; Schlosser & Anderson, 1994; Sherritt & Basom, 1997). Numerous studies in the field of distance education have focused on the comparisons of student performance in distance-education courses versus traditional face-to-face courses (DeLoughry, 1988; Souder, 1993). The general conclusion reached by these investigators is that there is "no significant difference" between the performances of students in distance-education courses compared to traditional face-to-face courses (Russell, 1999; Schlosser &

Anderson, 1994). More recent research efforts have focused on student attitudes rather than the previous emphasis on student performance (Biner, et al. 1994). Biner, Dean and Mellinger (1994) contend that student satisfaction play an important role in determining the success of distance-education courses. The authors argue that sustaining positive student attitudes can result in a number of student benefits such as lower student attrition rates, and higher levels of student motivation.

The Study

This empirical study surveyed 128 students enrolled in 29 courses offered entirely over the Internet to determine the dimensions which underlie student satisfaction with Web-based courses and examined how these dimensions can be used to predict student satisfaction levels. This study also examined the relationship between demographic variables, such as gender, year in school, students' prior computer, e-mail and Internet proficiency, as well as, Web-based course experience and their satisfaction levels with Web-based courses. This research attempted to provide valuable information on the factors that influence the satisfaction of students participating in Web-based courses. The intent of the researcher was to obtain results from a quantitative study that would guide in the design and development of Web-based courses that would fulfill the needs of distance learners, thus ultimately leading to their success in distance-education courses.

The participants consisted of students who were enrolled in 29 Web-based courses in the University of Hawaii system, Hawaii Pacific University, Baker College, Michigan and Nova Southeastern University, Florida for the Fall 2000 semester. The 29 courses spanned a wide range of content areas: two Anthropology courses, one Astronomy course, one Biology course, four Business Management courses, six Computer courses, three English courses, two Educational Technology courses, one History course, one Japanese course, one Journalism course, three Mathematics courses, two Medical courses, and two Political Science courses.

Survey Design

A review of the existing literature on student satisfaction with Web-based instruction, distance education courses and general student course evaluations yielded eight dimensions and 47 question items for the survey questionnaire to ascertain the factors that underlie student satisfaction with Web-based courses. The eight original dimensions were instruction, instructor's aspects, management/coordination, technological characteristics, interaction, experience with system, workload/difficulty and expected/fairness of grading.

The survey questionnaire was divided into two sections. In Section A, students were given a list of 47 statements that addressed the eight dimensions that could potentially affect their satisfaction with Web-based courses. For each statement, students were asked to evaluate the extent of their agreement with each statement. Throughout the survey instrument, a five-point, Likert-type scale ranging from "Strongly disagree" to "Strongly agree" was used. In Section B, students' satisfaction, demographic and individual information was collected. Student satisfaction was measured based on students' responses to two survey questions: overall satisfaction with the Web-based course, and comparison of the course with traditional face-to-face classroom courses (DeBourgh, 1999). Information about students' prior experience with computers, the Internet, e-mail and Web-based courses was gathered. Demographic data collected included gender and year in school.

Procedure

A letter to solicit for survey participants was sent via e-mail to 29 professors who taught Web-based courses, who then forwarded it to their online students. Recruitment of participants was on a voluntary basis, although some instructors provided additional incentive for students to participate in this study by offering extra course credits for completing the survey. The primary method to obtain data was through an online survey questionnaire that was made available to the students from December 11 to 23, 2000. Overall, there were 508 students in the 29 Web-based courses surveyed. A total of 128 usable survey submissions were received, giving a response rate of 25.2 percent.

Data Analysis

All data was analyzed with the use of the SPSS® Version 10.0 for Windows statistical software package. Prior to any data analysis, negatively phrased items were first transformed to ensure comparability of data. Descriptive statistics such as means and standard deviations were calculated for the student satisfaction variables, levels of satisfactions, and the demographic data collected.

Factor analysis was performed on the 47 variables that were expected to underlie student satisfaction with Web-based courses to establish the major dimensions of online student satisfaction. Varimax orthogonal rotation was used. After applying factor analysis, the study examined the relationship between the dimensions of student satisfaction and the overall student satisfaction. Stepwise multiple regression was used to identify dimensions that significantly predict overall student satisfaction with Web-based courses. The dependent variable was a summated scale that consisted of two items: overall satisfaction with the Web-based course, and comparison of the course with traditional face-to-face classroom courses (DeBourgh, 1999). Independent variables were the five dimensions extracted by factor analysis. In addition, t-test and univariate analysis of variance (ANOVA) were used to answer the other research questions in this study.

Results & Implications

Of the initial 47 items in the original survey, only 26 items emerged after factor analysis was performed and they loaded on five factors that were named – interaction, instructor, system-wide technology, workload/difficulty, and function-specific technology, see [Table 1]. The interaction factor was comprised of seven questions measuring respondents' satisfaction with the interaction they experienced throughout the duration of the Web-based course. The instructor dimension was comprised of six questions that measured respondents' satisfaction with the instructor of the online course that they took. The three items that comprised the workload/difficulty dimension measured students' satisfaction with the workload and the level of difficulty of online courses. The system-wide technology dimension included six questions that addressed the general technological aspects of Web-based course systems, such as ease of access and navigation, "user friendliness", online enrollment/registration, and assignment submission. The function-specific technology dimension consisted of four items that dealt with specific technological functions or features that are common to most Web-based course management tools, such as online grade book, assessment, audio/video components, and online lecture presentations.

Dimensions of Online Student Satisfaction

Dimensions	Number of Questions
Interaction	7
Instructor	6
System-wide technology	6
Workload/Difficulty	3
Function-specific technology	4

Table 1: Five dimensions of online student satisfaction involving 26 question items

Regressional analysis performed revealed that the five proposed dimensions of online student satisfaction were related to overall student satisfaction. Overall student satisfaction is apparently influenced primarily by four dimensions: instructor, system-wide technology, workload/difficulty and interaction. None of the demographic factors examined, such as gender and year in school, had any significant impact on overall student satisfaction with Web-based courses. Similarly, students' prior experience with computers, e-mail, Internet, and Web-based courses did not have any significant impact on overall student satisfaction.

The implication from the results of this study is that instructors of Web-based courses may be able to increase their online students' satisfaction by addressing the appropriate factors underlying student satisfaction. For example, it may be possible for online instructors to alter how satisfied their students are with this aspect of their online course by providing more timely feedback, and making themselves more accessible to their students. Additionally, student satisfaction with Web-based courses could be improved by ensuring that general technological aspects of Web-based course systems, such as ease of access and navigation, are improved. Biner, Dean and Mellinger (1994) argue that student satisfaction plays an important role in determining the success of distance-education courses. Therefore, understanding these factors that underlie online students' satisfaction can lead to increased success of online courses.

A New Policy Context

This is how the head of the US House Telecommunications and Finance Subcommittee, Rep. Edward Markey, described his role as a key policy maker in 1994. . It is an cautionary statement, reflecting graphically the type of shell shock we have witnessed among teachers, principles, boards, and bureaucrats involved in education policy-making across Canada, even today.

An information revolution has shaken the world. The effects of this revolution are visible on micro and macro levels-- from the details of the way people live their lives every day, to the highest decisions of government. The *Economist* (1996) put it this way: "by reducing the cost of communication, IT (information technology) has helped to globalise production and financial markets. In turn, globalisation spurs technology by intensifying competition and by speeding up the diffusion of technology through direct investment. Together, globalisation and IT crush time and space.

Most countries are greeting the emerging communication technologies with new sets of globally harmonised regulatory and economic policies. In the formulation of these policies, they are facing the simultaneous turmoil induced by a series of related fundamental global trends: world-wide policy deregulation in telecommunications, the collapse of traditional national market barriers, economic concentration in truly transnational companies, and breathtaking technological innovation, as communication technologies converge into a digital sea.

This has led to profound questions about the role and nature of policy itself. Are the old values attainable -- or even desirable-- anymore? Policy makers everywhere have begun to find their traditional policy contexts inadequate, indeed irrelevant, to their work.

Policy decisions are crucial here. But never have policy makers seemed so overcome with events, so dazed, in such disarray. The information revolution has challenged the functions and capabilities of policy itself.

Policy is that set of written and unwritten rules and guidelines which institutionalise and put into operational forms the social contracts which define our institutions and organisations. Policy is at work at both macro and micro levels of governance and control: in government at all levels, and in virtually all other public and private institutions, including our universities and our school systems. Policy addresses both institutional procedures and institutional goals. It provides a framework for the structure of decision making within an organisation, and it rationalises the decision-making process in the context of substantive and idealized value sets which represent the goals of the organisation.

Policy can take progressive or conservative forms. In its progressive aspects, policy will be flexible and it will map and steer the development of the organisation in light of evolving

Implementing Library Instruction for Freshman Composition on WebCT: The Oakland University Experience, 2001/2002

Frank J. Lepkowski
Kresge Library
Oakland University
United States
lepkowsk@oakland.edu

Abstract: In 2001 the library at Oakland University decided to supplement classroom instruction for freshman composition classes with WebCT modules. This web-based instruction included library basics, using the Voyager catalog system and an introduction to the FirstSearch databases. Using this new instructional modality caused striking changes in the relationship between the library faculty and the Rhetoric program, in the librarians' practice of classroom instruction, and in students' perception of the learning outcomes. Librarians were extremely ambivalent about the WebCT instruction and came close to canceling it for the next academic year; Rhetoric faculty consistently evaluated the WebCT module more favorably than the librarians' classroom performance; students frequently approached their library instruction after WebCT with an assumption that they had already learned whatever was needed through online instruction. The most successful outcomes came when a.) librarians and Rhetoric faculty collaborated closely; b.) Rhetoric faculty ensured that their students completed WebCT before arriving in the library; c.) librarians forged ahead with new content in the classroom instead of reviewing what had been covered in WebCT; d.) the students arrived in the library ready to do research with a topic area for investigation already identified.

Introduction

Oakland University is a growing suburban commuter university located in Rochester, Michigan, some 25 miles north of Detroit. Historically the library has been quite pedagogically active, teaming with other teaching faculty to deliver course-related instruction that in recent years has reached more than a quarter of Oakland's 16,000 students annually. In 2001/2002 the library joined in the University's campaign to use WebCT to deliver online instruction. What follows herein is an admitted unscientific yet, it is to be hoped, objective and analytical report on the program's effects on students, writing faculty, and the librarians.

Organizational Context

At Oakland University, all students are required to take a sequence including Rhetoric 160, or Composition II, the crowning focus of which is the consummation of writing a research paper. For many years, the library has provided a full week (roughly 3.5 hours of class time) of instruction in research techniques for this course. In 2000/01, due to the increasing number of sections and a static number of librarians, the library was forced to reduce its contact hours per section from 3.5 to 2. After teaching for one semester with greatly curtailed content, the library attempted to replace some of the lost instructional time with a library instruction course using WebCT.

The University had committed itself to WebCT some time previously, and was sponsoring a big push to have instructors create content for online courses. Over the course of summer 2001, a WebCT module was created covering the basics of library layout and procedures, basic searching in the online catalog Voyager, and introduction to the use of FirstSearch full-text article databases. In order to deliver this to all Rhetoric students, the decision was made to create a WebCT course for each Rhetoric section, into which the library module was then inserted. Previously an online course would only have been created on a individual basis for those sections of Rhetoric where the instructor wanted to develop online material.

Thus the adoption of this module of online library instruction resulted in the web-enhancement of the whole Rhetoric program, including the classes of many instructors who were not otherwise interested in web development.

In particular the Rhetoric faculty had the essential role of ensuring that the students in each section had absorbed all of the online content before arriving at the library for 2 contact hours of classroom instruction by a librarian. Many of the rhetoricians were first-time users of WebCT and were it not for us would not have been placed in the position of having to be familiar with it. The library held training sessions for them and distributed assistive documentation both for the instructors and their students. As can readily be imagined, we found widely varying degrees of commitment to or even understanding of this task among the 30 or so Rhetoric instructors. Similarly the library faculty also needed training in the use of WebCT. Everyone involved was forced to come to terms with this new manner of delivering instruction.

Consequences of Implementation

For the librarians, the creation of this WebCT component altered fundamentally aspects of the pedagogical situation. For the first time, we had to assume prior knowledge on the part of our students, the absence of which had been axiomatic to (and a realistic basis for) our previous manner of instruction. In fact we were forced to make a great leap of faith that in fact the students would actually *learn* from the WebCT module and would bring to the library with them a base level of knowledge upon which we would build. This assumption led us into two principal and somewhat paradoxical areas of difficulty.

The first difficulty was with ensuring the students' completion of the WebCT portion of the class before arriving in our classrooms. Some of our colleagues in Rhetoric were most wondrously effective in extracting compliance from their students, and in sections like that we had 80-100% completion rates. In other sections the instructors showed minimal commitment to this goal, with the result being that some sections would arrive with only 5-20% having done the assignments. Occasionally we found a section where nary a blessed soul had done so, and not infrequently we considered a success a class with a 50-60% completion rates.

The conundrum for the librarians given this wide variance in the amount of preparation by our students was that of choosing a level to pitch the class to in our instruction. We librarians are a service-minded crew and we hate to have any lambs stray from the flock as we guide them through the steep paths and perilous desfiles of the research process; there is also the matter of confronting slack-jawed incomprehension as we try to forge onward. We had been used to trying to sense the level of our audience and calibrating our approach to what we found there; now we had an expectation which we were powerless to enforce upon which the level of instruction was predicated. The more hard-nosed librarians proceeded with planned instruction assuming the students had done the required preparation, and those more sensitive to the gulf of understanding tried to compromise by reviewing content from WebCT to a greater or lesser extent related directly to the incomprehension level in the class. This created not infrequently a profound resentment among those students who had done the work, and the faculty who had made some efforts to ensure their having done so.

The second difficulty was paradoxical in relation to the first. For a certain category of students it seemed that completion of the WebCT module conveyed not the gratifying sense of having learned the bare minimum necessary to begin library research, but rather an illusion of mastery of the topic which made further instruction otiose. Thus it was that some of these students became resistant to further instruction and did not seemingly understand how rudimentary their searching skills still were. A question for further inquiry is whether completion of online instruction leaves the student feeling he or she has learned more than the old, in-person mode of conveying knowledge—a prospect which cannot help but cause an tremor of uncertainty in even an experienced teacher's breast. In our experience it seemed to create resistance to further learning in some cases. It is perhaps not surprising that given the difficulties of implementing the new program and the uncertain position occupied by the librarian with respect to the material that a certain amount of resentment and negativity towards WebCT began to occur.

As the academic year ended, the library faculty considered the future of WebCT instruction and the Rhetoric faculty were asked to contribute to a frank assessment of the effectiveness of the library instruction program. Evaluation of the WebCT library module was consistently positive and its continued use strongly backed, which rather surprised us considering how negative our own view of it was. In fact, the rhetoricians were overall less positive about the classroom performance of librarians. This was especially true when librarians had been seen to cover material in class which had already been done on WebCT. Both the students who had done the work and their instructors who had worked energetically to ensure that they had felt betrayed by librarians' concession to the ignorance of the irresponsible students. Clearly librarians need to make adjustments to their instructional practice to capitalize on the opportunities offered by online instruction, by accepting the accountability of students for their work, and proceeding from the WebCT content as a starting point.

Practices Conducive to Success

Through discussion among the librarians, and also with the Rhetoric faculty at their retreat, elements were identified which seem to be essential to successful library instruction in the current environment. *First,* a close working relationship between the librarian and the rhetorician is extremely important. They need to be communicating well before the class comes to the library, working on the goals for the classroom instruction, sharing information about the topics of student research. *Second,* it is essential that the Rhetoric instructor require the students to work the WebCT module, preferably with a grade attached to it; students seem to take more seriously schoolwork that is in some direct way involved with their GPAs. The librarian should assist in this process by monitoring the progress of students in a section and informing the Rhetoric Instructor when there are laggards as the date for classroom instruction approaches.

Third, students must have a sense of their research topic before receiving the classroom instruction in the library. To see that what they have to learn is meaningful to them, even after having completed the wonderful WebCT module, there needs to exist a clear and ineluctable link between what they need to do for the instructor who will be giving them their grades, and what they have to learn in the library. The most reliable predictor of a successful, productive library session is when students have an impetus and specificity to their research needs. *Fourth,* librarians need to accept students' accountability for their actions and resist the temptation to cover basics that should have been learned through WebCT. The best means of doing this seems to be minimizing the amount of exposition at the outset of the library classroom teaching, and instead involving them in practical searching exercises involving their own research topics.

Thus, in order to be successful, course-related library instruction through WebCT needs to rely upon a close and committed collegial relationship between the librarian and the instructor of record, potent incentives for students to actually do the work, and classroom followup which is directly related to their research projects. In this blended mode of instruction, as rhetoricians are obliged to ensure students undertake the basic level of library instruction, so librarians are obliged to adapt their classroom practice in the light of a presumption of student accountability. Both sides of the instructional team benefit from this, as do, most importantly, our students.

social perspectives and goals. In its more conservative aspect, policy tends to entrench established institutional practices and power relationships in favour of stability.

Conservative policy becomes dysfunctional when it works against the recognition of the underlying changing realities of an organisation, and in favour of protecting the status quo. Dysfunctional policy assumes that the agreed-upon procedures and goals are fixed and natural—it denies the reality of the institution or organisation as an historical reality, and denies its own role as the operational form of evolving social and institutional relations. A conservative policy is dysfunctional when it is used to defend bad decisions on procedural grounds, when it is used to bolster an institution and its powers against beneficial change and evolution, when it becomes exclusionary and non-inclusive.

But policy breakdowns can occur at the progressive end of the spectrum as well. A progressive policy becomes dysfunctional if it is too far out front, if it is uninformed, short-sighted, pressure-group driven and non-inclusive.

Policies addressing the information revolution are largely meant to be progressive policies by their implementers—that is, they are intended to map, steer and facilitate institutional change in light of the promise of a technological and economic revolution. They are often "out-front" policies, leading social change.

Education Policy: The Global meets the Local

The "education revolution" must be understood as a critically important part of a more general information revolution—one front in a larger campaign. In this micro realm we find the same transformation of policy and the same transformation of values which we which find in the larger macro-economic and information policy spheres.

Policies addressing the implementation and use of new technologies within education find themselves firmly entangled within overall information and economic strategies. Increasingly, education policies find themselves straddling boundaries between educational and economic objectives, even subordinate to them. The "ivory tower," if it ever existed, exists no longer. (See also *The Tower Under Siege*, Brian Lewis, Richard Smith, Christine Massey, McGill-Queen's University Press, 2002)

In our work we have identified and clarified some of the most pressing issues arising from the implementation of computer-based technologies in schools. These questions include: technological, infrastructure, human resource and learning policy issues; questions of sustainability; questions of gender; and questions of public policy in an increasingly technocentric and commercial education environment.

Each of these issues speaks to the need for strategies designed to address how and why choices are made, who makes them, and to what effect, both intended and unintended. Too often the reverse happens: technology changes rapidly and decisions are made in a more or less ad hoc fashion, as administrators scramble in response to the initial promises of technology. And then these same administrators, as well as teachers, students and parents, must face unforeseen problems and demands triggered by its implementation. The cart drives the horse.

There is a critical need for an approach to the implementation of technology in our schools that pays attention to questions of policy, organizational culture, politics, and decision-making practices. That is the approach we have taken in our work. Technology for whom, why, when, where? What value does technology add to the educational experience? How are the decisions made? By whom?

These can all be understood as "local" questions, grounded in the needs of real people, in real circumstances and real contexts. Yet these local questions-- answers to which we believe are key to the successful implementation of any plan for education, technology or otherwise-- are too often subsumed by the global issues, objectives, and assumptions of plans to develop "knowledge workers for the knowledge economy."

In fact, it is as if a major social fault line has shifted: there has been a shift in our relationship to almost all social activity—which seems increasingly judged and evaluated against a touchstone of macro-economic objectives and priorities. Education has not escaped this shift. If education had once been an objective, a goal, a final cause, for many of its leaders, movers and funders, it has now become much more purely a means to the end of a more efficient and competitive economy and workforce, captured within the notion of the "knowledge economy."

Is policy important?

Our fundamental notions of the purpose and value of education have been drifting, migrating from a primary interest in civic, moral and individual development, from service to families and communities, to the interests of a developing economic and technological infrastructure. Education as a goal in itself, and as a vehicle for the development of the individuals and citizens has been largely devalued in the context of these global changes. Technology policies tend to reflect this shift in basic assumptions: technology policies for schools have been developed, implicitly or explicitly, in alignment with a larger, fundamental shift in values which tends to privilege economic activity and technology as ends, and which tends to favour one-size-fits-all solutions to diverse problems.

But while policy drift reflects social drift, it is not a one-way process, nor is it a simple, one-on-one relation. The global never entirely subsumes the local and the particular. The local is always grounded in the reality of peoples' lives, and it is always potentially a site of resistance and creativity. Policy decisions made at the lower levels—the classroom, the school, the district, the region-- feed back in to the system, and ultimately help determine the direction of change and the velocity of change. And the way in which policy decisions are developed encourages or discourages the buy-in of its participants and stakeholders. Ultimately, local policies assure or discourage the sustainability of change.

Policy-makers and administrators at the school, school district and governmental levels have a decisive impact on the direction of any school reform (Glennan, 1998). Parents are also important: often the key driver for technology in the classrooms, parents need information to judge the educational "value" of different types of learning resources. They would ideally be part of the policy-making process. And in the classroom, teachers must be given the ultimate responsibility for determining the appropriate application of these tools. It is where we find this type of process that we find successful technological implementation and practice.

Technology Policy for Canadian Schools

The overall picture we would paint of a progressive, healthy policy-making process for education is one in which an enabling, supportive context for experimentation comes from the top, while specific applications and innovations coming from the bottom, fully grounded in an understanding of local learner needs.

Policy makers must first ask WHY? What is the vision, the reason for change? What are our goals? Where do we want to go? These are the fundamental questions which should be driving technology policy for our schools. Defining and co-ordinating this vision is the first task of policy leadership. Provinces should have technology plans, with clear goals. Boards should have plans. Schools should have plans. And good planning should be rewarded with resources, up and down the chain. These plans have to be grounded in local and regional concerns: what do what do we want our children to learn? What works best as a learning strategy, a learning technology — why and for whom?

Policy makers must see technology as a means, not as an end. They must adapt a VALUE-ADDED approach to technology. There is no single solution because there is no single problem. Technology-enhanced learning must not be understood as a alternative to the traditional and legitimate teaching, training, service and community functions of a school, but as a way to add value to each of these functions in specific cases. How can the introduction of technology enhance learning, help build community and citizenship, expand the horizons of our learners, add value to the education experience and help us achieve our traditional educational goals, as well as new objectives?

Policy makers must ask HOW? A transparent and inclusive policy process is essential. At each level, managers needs to think carefully and consciously about the appropriate process for the development of policy. These processes need to be seen to be, and in fact must be, transparent and inclusive. They must locally appropriate—fit the institution and its history and culture. They must embody local/regional knowledge. They must include an implementation strategy. We are no longer entirely pioneers—we have a considerable body of successful and unsuccessful practice in front of us and we can learn from those examples. A first step should always be to attempt to foresee the problems, generate possible best practices, critique these practices in light of the local circumstances, and attempt to generate local solutions.

And finally, policy makers must be prepared to ask WHAT IF? We must reward experimentation, make room to play and grow, make room to fail. We need to increase the critical mass of examples of successful practice, at the local level. Good teachers teaching great courses, made better through new tools. Schools should encourage and legitimize innovation, create an environment which encourages risk-taking, and publicize it. The end result should be a critical mass of good examples, well publicized—as well as mistakes made and lessons learned (equally valuable). Policies have to be formulated which support innovation and make it sustainable, once achieved— incentives for innovation, professional development policies and policies designed to sustain both the technical and human resource infrastructures which are required.

A transparent and responsive policy practice combined with a value-added approach to technology will enable teachers to feel in control of these technologies, and encourage them to become innovators themselves, in their own attempts to fulfil the goals of their professional practice.

Enabling open network access during exams

Michael Chiles, Luby Liao, John Paul, Jeff Wright
University of San Diego
San Diego, CA 92110
mchiles,liao,jpl,jhwright@sandiego.edu

Abstract This paper presents our experiences of giving students open network access during exams while guarding against cheating. The practical information presented should be of interest to would-be practitioners and technological conservatives who can test their pedagogies with an aim to give their students the best education while ensuring academic integrity.

1. Introduction

A question frequently asked by instructors in an increasing number of disciplines is how to give an exam that allows students limited and controlled access to the Internet from classroom computers. The following question posted on the ACM SIGCSE Forum mailing list on May 5, 2002 is typical:

'Has anyone tried giving a programming exam for some of your intro-level courses in a lab? I always get complaints from students that it is not fair to write code on a piece of paper without using the tools they normally use (and they are right about that). So, I want to block a lab for 2 hours, and assign a few programming problems to work out, and let them do it. However, I want to somehow avoid them sharing efforts, so that might means having every machine disconnected from the network. What other issues are there? Has anyone tried this? Has it worked? Do students do better than in paper exams? ...'

This paper details one possible solution to this problem in the context of an Engineering Math course. Our approach addresses the poster's problem without disconnecting machines from the Internet.

In the Spring semester of 2002, Jeff Wright taught two sections of Math 110A: Engineering Math using Maple 6, a well-known computer algebra system in a lab equipped with Apple Macintosh computers. To run Maple, each computer must obtain a license from a remote license server which limits the total number of Maple users on the USD network at any given time. While students use Maple in class and during exams, they are encouraged to access the class web site where Jeff maintains copies of relevant Maple worksheets and other items of interest. To summarize, Jeff's problem is to allow students access to the remote license server and the class web site, but disallow other uses such as chat, email, instant messaging, and other unauthorized Net access.

On the flip side, the ideas presented here may be useful to people who for one reason or another believe that giving students any network access during an exam is a bad idea for pedagogical reasons other than the possibility of cheating. Our approach allows these hypotheses to be tested in a more direct way.

2. A conceptually very simple solution

Our solution is outlined in the following steps:

Publicize network access policy to students. Students are told that that they can use Maple and access the class web site during exams. Other intentional outbound traffic such as emailing is considered a violation. We further tell students that during an exam the inbound and outbound traffic of their machines will be captured and later analyzed for evidence of violation.

Exam time reconnaissance. During an exam, we record students' communication in the form of IP packets with other computers. The result is stored in a file that typically amounts to megabytes in size.

Post-exam analysis of the captured network traffic. Using the multi-megabyte file obtained in step two, together with the web access log of the USD web site, we generate various reports to identify possible network access violations.

3. Miscellaneous considerations

The campus network at USD is based on secure switched Ethernet, effectively transforming traditional Ethernet from a broadcast technology to a point-to-point technology. In this case the only packets a machine can normally see are its own and those broadcast packets sent by other computers in the same local area network. Hence, the arbitrary sniffing of all IP traffic on the network described above cannot be implemented until the campus network administrator performs a configuration procedure known as port mirroring [2]. Port mirroring involves copying all packets in and out of all the monitored machines to a specific monitoring machine, known as the 'sniffer'.

A separate issue at USD is a strong privacy policy that prohibits unauthorized sniffing of IP packets. We address this by performing the following steps before giving an exam we wish to monitor:

- request that the network administrator performs port mirroring to enable exam time reconnaissance.
- notify Academic Computing that we will be sniffing packets during exams.
- let the students know that we will be sniffing their packets during exams.

4. Technical details

1. First, we obtain a list of the Media Access Control (MAC) addresses of the classroom computers from the campus network administrator. Every campus computer connects with the campus network using an Ethernet card. Every Ethernet card has a permanent and unique MAC address of the form `hh:hh:hh:hh:hh:hh`, where `h` is a hexadecimal digit. Note that 'MAC' should not be confused with the Apple Macintosh computer. The relevance of MAC addresses lies with the fact that our lab computers obtain their IP addresses from a DHCP server when they are powered on. These IP addresses are dynamic as opposed to static because they can potentially change from time to time rather than staying fixed. MAC addresses, on the other hand, remain fixed and serve to identify the computers and the students using them.

2. Immediately before the exam, we run the following command on the designated 'sniffer' computer on the same local area network running Redhat Linux 7.2:

```
tcpdump ether host 00:05:20:C5:67:40  or 00:05:20:96:3F:2E or ...
```

Note the use of MAC addresses to specify the monitored machines in this command, rather than the potentially transient dynamic IPs. Here '...' stands for the remaining long list of other MAC addresses. What follows the `tcpdump` command is an example of a filter expression. In practice, since the filter expression is very long, we use a more convenient form:

```
tcpdump -F tcpdump_exp
```

where `tcpdump_exp` is a file that contains the filter expression and `-F` instructs `tcpdump` to read the filter expression from the file. This command will capture all inbound and outbound packets from all the machines listed in `tcpdump_exp`.

Tcpdump is a freeware packet-sniffing program available for Unix and Windows machines. Tcpdump can be installed with the following simple rpm command on computers running Redhat Linux:

```
rpm -Uvh tcpdump-3.6.2-12.i386.rpm
```

A fragment of the output from the `tcpdump` command follows:

```
07:29:09.967237  xyz203.sandiego.edu.1612  >  www.sandiego.edu.http:  P
607407960:607408445(485) ack 2259258923 win 32768 (DF)
07:29:09.973142  xyz203.sandiego.edu.1611  >  www.sandiego.edu.http:  P
607340903:607341388(485) ack 2259236870 win 32768 (DF)
```

The first line says that at 7:29 AM, the machine `xyz203.sandiego.edu` sent a packet from its port `1612` to the USD web server machine `www.sandiego.edu` which listens on the well-known port `80`, symbolically named `http`. '>' visually indicates the direction of the communication. For details of the meaning of the output line components, we refer the readers to the documentation for `tcpdump`, and [1].

Even though we specify MAC addresses in the `tcpdump` command, the `tcpdump` output identifies machines using their DNS names and not MAC numbers. At USD the DNS names of the monitored machines are programmatically mapped to their dynamic IPs in an intuitive way. For example, `xyz203.sandiego.edu` has IP address `192.215.84.203`. Thus, we need a table that maps the MAC address of each machine to its dynamic IP during the exam. We use another freeware packet sniffing program called `ettercap` to produce this table. The command is

```
ettercap -Nl
```

The output columns, aside from the first, are IP address, MAC address, and fully qualified domain name of each lab computer:

```
14) 192.215.84.172        00:05:02:37:24:9F      xyz172.sandiego.edu
15) 192.215.84.190        00:05:02:F5:2B:04      xyz190.sandiego.edu
16) 192.215.84.205        00:50:E4:05:DA:55      xyz205.sandiego.edu
17) 192.215.84.207        00:05:02:1E:D0:6F      xyz207.sandiego.edu
```

3. The final step is to analyze the `tcpdump` output. Visually scanning it is instructive, but since the readable output file is megabytes in size, it is useful to write scripts to generate reports from the `tcpdump` output file. We used the Python programming language to develop these scripts, but any language with strong text processing support, such as Awk or Perl, could be used. As an illustration, we show fragments of two HTML reports we generated. The next two tables in the first HTML file report on two machines, `xyz157` and `xyz159`. These tables show outbound traffic of each machine. The three columns of the tables are the source port used, the destination machine and the destination port.

Outbound traffic from xyz157.sandiego.edu

src port	destination	dst port
netbios-ssn	lsanca1-ar22-4-33-006-054.lsanca1.dsl-verizon.net	2463
1857	http://www.sandiego.edu/	http
netbios-ssn	adsl-66-125-108-220.dsl.scrm01.pacbell.net	2487
netbios-ssn	66-105-104-140.customer.algx.net	2843
1861	http://www.sandiego.edu/	http
Bootpc	dhcp1.sandiego.edu	bootps
1865	http://www.sandiego.edu/	http

Outbound traffic from xyz159.sandiego.edu

src port	destination	dst port
netbios-ssn	lsanca1-ar22-4-33-006-054.lsanca1.dsl-verizon.net	2459
netbios-ssn	adsl-66-125-108-220.dsl.scrm01.pacbell.net	2483
netbios-ssn	66-105-104-140.customer.algx.net	2839
http	211.219.112.180	3267
Bootpc	dhcp1.sandiego.edu	bootps
netbios-ssn	HSE-Ottawa-ppp240974.sympatico.ca	1798
netbios-ssn	64.128.149.45	1875
http	218.11.130.38	4820

Immediately we notice that the student machines contacted various *targets* that appear suspicious or require further investigation. To wit,

1. on line 1, `xyz159` talked to the server running on port `2459` of `sancal-ar22-4-33-006-054.lsancal.dsl-verizon.net`. Is this a violation?

2. on line 2, `xyz157` talked to the USD web server listening on port `80` (symbolically named `http`) of `www.sandiego.edu`. In this case, further investigation is needed to decide whether xyz157 was accessing Jeff's home page at `http://www.sandiego.edu/~jesper` legally, or someone else's web site such as `http://www.sandiego.edu/~cheater` illegally.

Note that in the first case, `xyz159` talked to its target using a privileged port `139`, symbolically named `netbios-ssn`. This contact was not initiated by the student and therefore does not represent a violation. In the second HTML report we generated, such irrelevant records are filtered out.

To answer the second question, a simple programmed scan of the USD web site access log will suffice. To emphasize the importance of this simple but essential procedure, imagine the following scenario. Student A prepared his cheating group by training the members to use Netscape editor to publish to a common web site http://www.sandiego.edu/~cheater. During an exam, all the group members open Netscape editor to constantly publish their solutions to the site for their members to see. A simple Unix command `grep` applied to the web access log will catch this.

As promised, the next HTML report excludes irrelevant information from the report.

Outbound traffic from xyz157.sandiego.edu

src port	destination	dst port
1857	http://www.sandiego.edu/	http
1861	http://www.sandiego.edu/	http
1865	http://www.sandiego.edu/	http
1865	http://www.sandiego.edu/	http
1870	http://www.sandiego.edu/	http
1882	http://www.sandiego.edu/	http

Outbound traffic from xyz159.sandiego.edu

src port	destination	dst port
49152	dns.sandiego.edu	domain
49158	ftp08.apple.com	ntp
1367	http://www.sandiego.edu/	http
1363	http://www.sandiego.edu/	http

Line 1 of xyz159's table is the result of a contact to the Domain Name Server of USD, typically triggered by a web page request. Line 2 is a request from xyz159 to ftp08.apple.com, a time server, to synchronize the computer's system clock. Neither of these packets could be used by students to carry out clandestine communications.

5. Conclusion

After the post-exam analysis, we found no evidence of cheating. We feel that our method is effective for empowering students while preventing them from abusing their power. This practice enriches Jeff's teaching method and benefits his students. Our successes have encouraged us to continue to work to improve and streamline our approach and to experiment with new ones. The Python programs we have written to generate the reports are not refined enough to be published, but they can be useful to some people as examples. Feel free to email `liao@sandiego.edu` to request copies.

Development of Web Server Surveillance Software

Introduction:

In early 1970s, David Bell and Leonard La Paula developed a model for secure computer operations. This model was based on the concept of various levels of classified information (Unclassified, confidential, secret and top secret) and various levels of clearance. If a person had a clearance level that dominated the classification level of a file, that person could access the file. If the persons clearance level was lower than the file's classification, access would be denied. This was used in the defense. The Trusted Computing System Evaluation Criteria (TCSEC) also known as Orange Book in 1983 defines Computer System accord in the following scale:

D-the minimal protection or not rated
C1-Discretionary Security Protection
C2-Controlled Access Protection
B1-Labeled Security Protection
B2- Structured Protection
B3- Security Domains
A1- Verified Design.

The other attempts are the German green Book in 1989, the Canadian Criteria in 1990, the information Technology Security Evaluation Criteria (ITSEC) in 1991 and the Federal Criteria in 1992. The concept was that common application environments could develop their own profiles for security functionality and assurance levels. The profile would then be used by some authority to certify the compliance of computer systems.

When Computers are networked together, new security issues arise and old issues arise in different ways. The Orange Book did not address the issue of networked computers. The Trusted Network Interpretation of TCSEC (TNI) took all the requirements of the Orange Book and attempted to address a networked environment of computers. Few systems were evaluated under TNI and it did not achieve commercial success. Hence it appears that none of the solutions by themselves solved all of the security problems. A good security system proposed is a mix of all of these solutions and many more. The intent is to prevent legitimate users from using the server for sending and spreading information harmful for the human society.

Security Essentials:

Computer security (COMPUSEC) is necessary to control access on our computer systems and Network Security (NETSEC) is needed to control the security of LAN. Together all of these concepts provide information Security (INFOSEC). Technology has progressed too fast for most of the proposed process. The anti virus software, Access controls like user ID, smart cards, biometric and Firewall are some preventive methods. A firewall cannot prevent an attacker from using an allowed connection to attack a system. If a webserver is allowed to be accessed it is vulnerable to an attack, since the user is already in the internal network.

Security Threats from legitimate users:

Intrusion Detection Systems (IDS) were once treated as the solution to the entire security problems. Intrusion Detection Systems (IDS) have existed for a long time. No longer it is needed to protect our files and systems, but just identify when someone was doing wrong and stop them. Some IDS have the ability to stop attacks before they were successful. No IDS is foolproof. They cannot detect legitimate users having incorrect access to informations. There are 2 types of IDS.

1.Host based H-IDS

2.Network-based (–IDS)

These have well defined criteria for what constitutes a penetration attempt and what constitutes the security perimeter. This perimeter can be defined by fire walls, telecom demarcation points,

The Defining Goals are :

- Detection of attacks
- Prevention of attacks
- Detection of policy violations
- Enforcement of use policies
- Enforcement of connection Policies
- Collection of Evidence

Proposed Web Server Surveillance:

The proposed Web server Surveillance System is shown in Figure.

Monitoring mechanism ensures that the users are constantly checked for the content of the traffic without violating the privacy policy. Policy Management schemes choose on what to monitor. IDS schemes are used to detect any malicious intent. Pattern Recognition schemes can be used for comparing with harmful patterns. Natural language Processing is also used.

When suspicious activity occurs, there are five steps that can be taken to determine the nature of the activity. These are:

1.Identify the systems using IP addresses.

2.Log additional traffic between Source to Destination.

3.Log all traffic from the Source S.

4.Log the contents of packets from the Source

5.Calculate the vulnerability and threat level.

Following each of the steps, a determination should be made as to whether sufficient evidence has been found to identify the activity as an attack.Choosing how to respond is critical. Setting Thresholds are necessary to compute Vulnerability and threat The response can be Passive response or Active response If the event occurs once and does not repeat, it is very difficult to confirm. Some anomalies are almost impossible to completely investigate.

GUI tools are used to prepare daily/weekly/monthly reports.

Conclusion:

This Web Server Surveillance Software will prevent users from wrong use of the powerful tool of Communication, the Internet. Also it will prevent Web Server hosts to monitor legitimate users indulging in spread of violence using the server facility.

The Effect of E-mail Project on Enhancing EFL Learners' Academic Writing Skills

Huifen Lin
Department of Adult Education, Instructional Systems, Workforce Education and Development
Penn State University
United States
huifen5612@yahoo.com.tw

Abstract: This paper aims to report the findings of a study conducted to examine if E-mail is an effective tool in enhancing EFL students' academic writing skills. The participants in this study consisted of 8 college students majoring in English as a foreign language in a senior college in Taiwan. Each student was assigned one or two key-pals from eight countries. The findings suggested that although e-mail was proved to be an "authentic communicative writing activity" (Weasenforth &Biesenbach-Lucas 1998), it provided little or no benefits in improving students' overall academic writing skills. However, Email exchange provides an authentic audience that promotes two-way communication and its spontaneous nature and "informal conversational texts"(Marcus 1995) responds to most EFL professionals' belief that language acquisition is more likely to take place when there is a purpose to communicate and there exists an anxiety-free circumstance to do so.

Literature review

With the advent of the era of information, new technologies have been explored extensively in the business, commerce and educational field regarding the effectiveness, potential applications and implications they can bring to benefit the life, work and learning of human beings. The impact of technologies on education has, in particular, received increasing research interest when gathering amounts of findings suggested that if appropriately employed, technology can enhance learner involvement (Warschauer,1996;Kelm,1992), promote collaboration among learners and provide learning environments or tasks that traditional classrooms cannot offer. Computer-mediated Communication (CMC), among other technologies, provides tools that vastly transform means and nature of communication which EFL instructors can take advantage of and integrate into a communication-oriented, learner-centered language classroom. The most appealing feature of CMC is its creation of learning environments in which communication can be engaged beyond geographical boundaries and time constraints. Asynchronous type of CMC, for example, e-mail and BB, involves interactions to occur at different times; on the other hand, synchronous mode, including chat, IRC, and MOOs, enables communication to take place at the same time (Sussex & White 1996).According to Murray (2000),CMC, as "a salient mode of communication" has taken on a new role as a facilitator in the English language learning and instruction. Overall, the realities and potential of electronic communication for reducing learner frustration, easing learning process and creating self-paced learning environment have been recognized through the 1990s by proponents for Communicative Language Teaching (CLT), a method that emphasizes the acquisition of communicative competence being the goal of language instruction. Many ESL/EFL professionals have conducted in-depth research on the effect of e-mail on language teaching, hoping to take advantage of the unique features of the electronic text that this medium generates to assist students' learning of the target language. Research findings do suggest the implementation of e-mail projects in L2 classroom improve students' participation (Kamhi-Stein & Browne-del Mar 1997) and furthermore, foster a "student-student interaction"(Ady 1999;Kern 1996).Sakar (2001) on his research on the cross-cultural effects of e-mail on EFL students also suggested that e-mail exchange provided foreign language learners opportunities to be exposed to both reading and writing practice of the target language and also had great influence on learners' perception and attitudes toward the target language culture and people. Task-based or content-based approaches have been a center of discussion among ESL/EFL professionals and instructors, who believe that by dealing with real-life activities or projects, students gain access to "authenticity"-authentic materials and interactions and become highly motivated, as opposed to the artificial or pseudo interactions created from traditional language classrooms (Wolff, Universitat &Wuppertal 1998). Compared to traditional snail mail, e-mail has become more and more popular with its obvious advantages such as the high speed, low cost and ease of editing and revising. Numerous websites nowadays provide service for people or institutions looking for key pals to conduct projects or collaborative works. These e-mail exchange projects or tasks create a process-oriented, learner-centered language learning environments in which students can practice their reading and writing and oral skills indirectly if the task is appropriately designed.

The Study

The setting for this study was a course titled "Project-based Language Learning" in a five-year senior college English department in Taiwan. A successful complement of the course will lead to partial fulfillment for a Bachelor's degree in language and arts. The course objectives include (a) to provide opportunities for meaningful use of the target language on a task or project basis (b) to integrate previously learnt knowledge in different disciplines such as international business, English teaching methodologies, survival English,etc into the project or task design (c) to recognize the value of collaborative work on the process of language learning and (d) to demonstrate to the department faculty that students have achieved a more-than-satisfactory level of English by successfully turning in the final product of the project and orally present and defense it in front of faculty members and their fellow students. After a preliminary research and productive brainstorming process, the class decided the topic of the project," You've got mail-multicultural exchange" and specified the objectives of the project as "to further improve our English ability, especially writing and reading skills. To be exposed to different cultures, accept them and then develop open-mindedness toward cultural diversity; to reduce conflicts resulting from misunderstandings and to try an alternative way to learn a language". (cited from the project preface written by students). This project included three major stages. First, the preparatory stage, the author guided students to log on the net and browsed websites for interested e-pals. Students were advised to look for at leas 3 e-pals from the target culture he/she was interested in and were practicing sending practice e-mail to each other and to the author before starting the e-mail exchange with international e-pals from U.S. Britain, Austria, Korea, Japan, Germany, Argentina and Sweden. The duration for this project was 3 months, covering 8 topics specifically related to culture. Each participant in the project was required to write and reply to each e-mail message at least one time per week. Second, students turned in off-line essays featuring the cultural topics of the e-mail exchange by making reference to the information given by their e-pals, materials collected from school library or searched from the Internet. At the end of the project, the author expected to receive 8 essays from each of the participants, which were then used to compared with the transcripts of the e-mail messages to examine any significant difference in speech registers employed in both types of writings and in particular, to identify the linguistic features employed in academic writings. Finally, questionnaire and interviews were conducted to draw students' feedback on this e-mail exchange project and the aspects of language learning students especially benefited from this activity.

Findings

64 essays and 64 e-mail messages from participants were analyzed according to the linguistic features or speech registers associated with academic writings specified in Table 1. Several insightful findings can be drawn here.

- Paraphrasing, summarizing and giving examples were composing techniques that were used more frequently in both writings.
- Quotation and supporting claims with evidence were two skills that were the least employed in both writings, compared to the other six techniques.
- In e-mail messages, it's easier to appeal to the emotions of the writers/readers as opposed to the paper-and-pencil essay writings.
- There was no significant difference in terms of the frequency of the speech registers associated with academic

writing used in both types of writings.

•The scripts of e-mail messages revealed more carelessly-made errors such as subject-verb agreement, spelling and run-on sentences that mostly would not take place in traditional essay writings.

Table 1: Number of occurrence of academic writing features

Note: PPH-:paraphrase; SM-summarize;QUO-quote;REF-making reference; PO-taking positions; EMP-giving examples; EVD-supporting claims with evidence; EMO-appealing to the emotions

Questionnaires and interviews conducted shortly after the project indicated that participants, in general, believed that e-mail as a writing tool (a) introduced them to a world that they can engage in real, authentic interactions, (b) motivated them to write more and regularly and overcome the language difficulties to get meanings crossed, (c) provided permanent records or resources that they can retrieve or make use of for later work, (d) allowed them to write for real readers/audience instead of writing for the sole reader- the instructor and (e) gave them opportunities to be in contact with more colloquial, informal or dialectal use of the target language, which would be otherwise impossible under the circumstance of traditional language instruction.

Conclusions

This study has shown valuable insights into how EFL students responded to the use of e-mail as a writing tool and the results appeared to suggest that although no significant evidence could be identified to prove that EFL learners improved their skills for writing for academic purposes via involving in the e-mail exchange project, it's still widely recognized that "e-mail provides a context-rich, meaning focused, authentic communicative writing activity" (Weasenforth & Biesenbach-Lucas 1998). Students demonstrated an unexpected level of involvement and enthusiasm towards communicating via e-mail to increase their cultural awareness and language practice opportunities. Cummins (2000) has provided a framework for academic language learning which suggests that focusing on meaning, language and use is essential in language instruction "in order to develop students' access to and mastery of academic registers". Email exchange provides an authentic audience that promote two-way communication and is spontaneous, natural and informal conversational texts responded to most EFL professionals' belief that language acquisition is more likely to take place when there is a purpose to communicate and there exists an anxiety-free circumstance to do so. To conclude, e-mail exchange activity could be appropriately integrated into language instruction given the features and advantages derived from this study; nevertheless, further research on its potentials in promoting language learning compared to other CMC tools can be conducted to provide instructional suggestions for EFL instructors..

A STRUCTURED APPROACH TO PROGRAM EXPANSION FROM ON-CAMPUS TO DISTANCE DELIVERY

Marilyn Lockhart, Richard Howard, Larry Baker
Montana State University
Bozeman, MT USA

Introduction

The decision at higher education institutions to expand programs and classes from on-campus to distance delivery often has not been made using a systematic, structured approach. Instead, the change at most institutions, particularly those with limited resources, has been driven by political forces, with state legislators, governing boards, and administrators issuing directives to implement the delivery of courses and programs through computer media. These mandates are passed on to deans and department heads, who in turn, look to faculty members to make distance delivery a reality. Arguments of resource savings and enrollment increases seem to be the primary motivation for these mandates. The directives have been presented with minimal consideration or understanding of the impact on faculty. Often, faculty are expected to design and deliver the courses under assumptions and resources similar to those of delivering on-campus classes. A recent review of selected institutions in a state university system revealed that over the past three years, the progress of transitioning from on-campus course delivery to on-line class delivery has been slow, often resulting in faculty and administrator frustration. Gaps between what administrators have promised external constituents and what faculty have delivered have been significant. As external expectations of distance delivery increase, institutional administrators are experiencing increasing pressure with limited ideas about how to enhance the delivery of on-line courses and programs at their institutions.

The purpose of this paper is to present a model of a structured approach to designing and delivering distance education. Adopting a structured approach to identify issues and solutions associated with the development and implementation of distance delivered courses and programs will result in enhancing the campus's ability to meet external expectations, while providing administrators and faculty with a mechanism to identify and recommend needed processes and required resources to deliver quality distance education.

Overview of Structured Decision Making

Structured decision support offers an avenue for the creation of sustainable and positive innovation, in this case, the expansion from only on-campus course delivery to on-line delivery. This structured approach enables college and university administrators to produce a link to faculty and students, increase performance, improve quality, and streamline processes that are easier to manage. Rational or structured decision support typically reflects analytical processes in which models are built that reflect various alternatives that a decision maker can make and assess potential outcomes. In general, these analyses are quantitative in nature and revolve around the relationships of factors/outcomes and related resources. While these models provide important information, their usefulness in the decision making process should be viewed as a starting point. A process of structured or rational decision making reflects the creation of information (quantitative and/or qualitative) that is integrated into the knowledge base of the decision makers and other constituencies across the campus. The results of this integration are the creation of intelligence, which is then brought to bear on the decision that needs to be made. In this process, the empirical information is analyzed, interpreted, and integrated into the knowledge base of the decision makers. The resulting intelligence is the integration of both the results of the data analysis and the decision maker's existing knowledge about the context in which the decision is to be made. Once a decision is made, assessment of the impact of the decision provides the campus with increased organizational intelligence. Critical in this process is the ability to access valid and reliable resource and productivity/outcomes data, and through appropriate analyses, create quality information that is communicated effectively to decision makers.

Using The Structured Approach to Distance Delivery Decision Making

Since the motivation for distance delivery often comes from forces external to the institution, mentioned earlier, often there is a resulting disconnect between administrators and faculty. This structured approach provides a method of eliminating this disconnect or gap between administrators and faculty, as well as providing an avenue for creating the knowledge and information needed for making decisions about distance education. The specific model presented below modifies and simplifies a business redesign process developed by the National Association of College and University Business Officers (NACUBO) and has been used by the authors for examining and improving other academic and administrative processes. The approach should function well in expanding higher education offerings from on-campus to on-line delivery.

The structured approach to making decisions about distance education should begin with several underlying mission values formulated and articulated by senior management. These would include the formation of partnerships between administrators and faculty, the delivery of quality programs and classes, and the use of technological and financial resources to their fullest advantage; all in support of the mission of the institution. The approach includes a three-tiered hierarchy, with continual communication among individuals in the different levels of the hierarchy.

The first tier consists of a "Steering Committee", composed of senior level administrators, charged with providing guidance and oversight to the institution-wide endeavor. Their role is to assess institutional readiness/administration, develop a long-range distance delivery plan, and approve policies, procedures, resources, and other support needed to move efforts forward.

The second tier is a "Process Owners Group" which consists of members from areas of the institution that are directly involved in the processes that "own" implementing distance delivery. Administrators and faculty from the colleges/departments and individuals from information technology center, faculty development, student services, and other key areas should be represented in this group. The "Process Owners Group" forms the work teams, writes project charges, and reviews and approves team recommendations.

The teams are composed of a mixture of faculty and administrators who are actually involved in carrying out the distance education initiatives. Some topics that teams might address include: faculty services, instructional design/course usability, student readiness and support, and student learning outcomes and retention. The teams could answer questions such as:

- How does the institution prepare the faculty pedagogically and technologically to teach on-line course? What improvements are needed in this area?
- What incentives are and should be provided to faculty?
- How do faculty need to be supported during instruction?
- How do we prepare students to take distance classes?
- How user friendly is the technology to students?
- What services, such as library, registration, and ongoing help is available to students? How effective are these services? What are the additional student support needs?
- How should we measure learning outcomes?
- What are the outcomes of distance classes?
- What are the retention rates of on-line students?

The groups operate as teams, rather than as committees, receiving training in team work and structured decision making. Potential team members are interviewed in advance of appointment to assess available time, commitment to the project, and the ability to be a "team player." Team leaders receive in-depth training on the structured approach to decision making and group dynamics. Characteristics of good teams, such as having clear and identified team roles and responsibilities, conducting open discussions, possessing high levels of trust, displaying cooperation and collaboration, exploring and confronting differences, sharing of decision making, and participating equally, are described and developed among group members by the team leader. Collaboration among teams and between teams and the rest of the campus is encouraged and fostered by scheduling communication/progress reports.

Teams may redesign current activities or create new ones. Practices at other institutions are researched and compared to the context of the home institution. Some teams may distribute surveys to key groups (internal and external) in order to obtain data related to distance delivery. Some may conduct interviews with key stakeholders to gather in-depth, detailed data. Following the structured decision making process, recommendations based upon these data are created. Each team is expected to design a business plan that includes personnel and resource implementation requirements, benefits, potential barriers, and an assessment strategy for each set of recommendations.

Plans are presented to the "Process Owners Group" and "Steering Committee" for final approval.

Conclusion

A structured approach to the development and implementation of distance delivery on a campus can eliminate the gap between external expectations and campus realities. Some institutions may discover they should move more cautiously towards distance delivery than others. A structured approach is more likely to be received favorably by faculty because realistic support requirements have been identified and recognized by administers and faculty. The result will be realistic expectations of a distance education program that is consistent with the campus's resources to support it. In addition, through this structured process, identification of the campus's capacities to deliver distance education provides substantive information for discussions with external constituencies about needed resources.

A Feedback Model and Successful E-Learning

Abstract: Based on the literature concerning feedback, self-regulated learning and cooperative learning, this paper discusses a model of effective feedback that can be used to support student learning in computer-mediated environments. The model portrays the learner and teacher/peers as actors who both provide and receive feedback in interlocking loops during learning activities. Findings from two illustrative examples in science and social science classes indicate that while e-learning settings offer the opportunity to enhance feedback during the learning process, effective feedback structures are not automatically a part of interactive simulations, computer-mediated communication or other e-learning settings. Effective feedback in e-learning requires careful design and experimentation.

Introduction

This paper discusses a model of effective feedback useful in supporting student learning in computer-mediated environments. The word feedback is often used loosely. In this paper we define feedback as an informational message sent by one element of a system to another element, with the expectation that the receiving element will use this message to modulate its performance. For example, a home heating system consists of thermostats, a control switch and a heat source. The thermostats compare room temperature to a predetermined desired temperature, and then send messages to the switch telling it to either turn the heat source on or off (Doig, 2000). Such a system is only functional if: appropriate messages are sent to the switch; the switch correctly interprets messages; the heat source responds effectively to the situation. Thus, feedback is a message sent with the intent of moving the recipient from a current state to a goal state. We will refer to effective feedback as feedback that meets four conditions: 1) feedback recipients have a clear understanding of the gap between their current state and their goal state; 2) appropriate corrective messages (feedback) are sent and received; 3) feedback is interpretable by its recipients; and, 4) recipients possess prerequisite prior knowledge, motivation, and strategies to respond effectively to the feedback. We will first describe our model of effective feedback that is rooted in research on: feedback, self-regulated learning, and cooperative learning. We will then describe two situations drawn from science and social science classes that will illustrate the differences inherent in computer-mediated learning environments and standard face-to-face settings, when viewed through the lens of our model.

A Model of Effective Feedback

From a constructivist perspective, learners build knowledge by cognitively elaborating new information, by reconciling with previously held views both the data gained through their own observation and experimentation, and through external feedback. Similarly, teachers as course designers function as self-regulating systems when they construct new task and feedback structures in a process involving elaboration and experimentation, as well as reconciliation of previously held views with feedback information provided by actions and performance of learners.

Research on feedback has accumulated a wealth of information concerning the impact of feedback on student learning. Several meta-analyses (*e.g.*, Bagert_Drowns et al., 1991; Azevedo & Bernard, 1995) synthesizing this research found that providing feedback versus not providing feedback has a significant positive effect on student achievement, however, the effects of elaborate feedback with explanation were generally found to be significantly larger than simple feedback without explanation. This research has primarily focused on external feedback, as provided by a teacher either directly or via a computer, after student performance.

Research on self-regulated learning (*e.g.*, Butler & Winne, 1995) suggests that learners generate internal feedback during the cognitive process of monitoring. Self-regulated learners monitor their own academic performance, affect and learning strategies. They rely on internal feedback to guide the selection of appropriate strategies and corrective action if their goals are not being met. They seek external feedback when they cannot resolve problems on their own.

Research on small group cooperative learning indicates significant positive effects of small group learning over whole class or individual learning if appropriately structured (Abrami et al., 1995; Lou et al., 2001) and that those who gave or received peer explanations tended to achieve higher than others (Webb, 1989). This research suggests that peers can be another source of external feedback.

Based on the above three areas of research as well as constructivist theories of learning, we have created a model of effective feedback that incorporates all three sources: self, teacher and peers (see Figure 1). In the model, learning/teaching involves simultaneous feedback loops, one centered on the learner and another (completed by the dashed line) centered on the teacher/peer. Solid arrows indicate feedback, while hollow arrows represent corrective actions in response to feedback. Note that a teacher's/peer's corrective action is simultaneously external feedback for the learner. To portray this duality we use both solid and hollow arrows flowing from the teacher/peer to the learner.

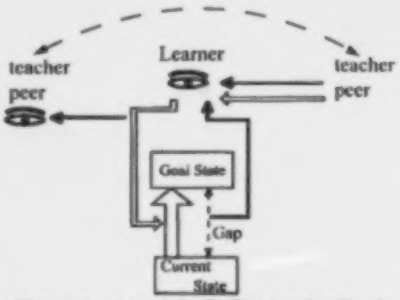

Figure 1. A model of effective feedback

In this model learners are viewed as active self-regulators, who seek feedback and then respond to it. Learners depend on the instructional setting to provide both the tasks from which they can draw data, and the feedback structures that allow them to gauge their performance (Pintrich, Marx & Boyle, 1993). In turn, teachers who create these same task and feedback structures need feedback from learners regarding the effectiveness of the structures. Thus, effective teaching depends on teachers being sent appropriate messages by the students; the ability of teachers to interpret those messages; and, teachers having appropriate skills to respond effectively to messages. That is, teachers, as course designers, form another self-regulating system that initiates changes based on feedback gathered from the actions and performance of learners. Alternatively, peers who offer constructive criticism, form another self-regulating system that interacts with that of learners.

While this model applies both to face-to-face and computer-mediated learning environments, there are vital differences in the type, timing, and sources of feedback used in these different learning settings. For example, in face-to-face classrooms, feedback to individual learners during the learning process tends to be short and simple due to time constraints. More elaborate feedback may be provided to the whole class, but targeting a mythical "average student". Public feedback aimed at an "average student" discourages and bores high-ability students while confusing less apt ones. However, when elaborate feedback is one-on-one, between teacher and an individual student, no student other than the individual involved in the interaction benefits. In the computer-mediated environment individual feedback need no longer be private, nor must public feedback be targeted at the "average student". For example, with discussion boards, public feedback provided by the teacher to an individual student can benefit other students with similar misconceptions. This knowledge motivates teachers to provide more elaborate feedback, which leads to higher performance standards in the class. On the other hand, teachers and learners in face-to-face settings have the advantage of synchronous verbal and non-verbal communication. In face-to-face settings, a good instructor constantly "reads" the class and modifies instruction to maintain student involvement. In computer-mediated settings this type of information is absent and new ways of "reading" involvement must be used.

With two very different e-learning settings, one in science classes using Web-based computer simulations,

BEST COPY AVAILABLE

and one in social science classes using Web-based discussion boards, we will illustrate and draw lessons concerning the interlocked loops of learner and teacher; and then the interlocked loops of learner and peer.

Feedback and Web-Based Simulations

Interactive simulations are frequently used in computer-mediated instruction with the intention of allowing learners to rapidly generate many "instances" of a particular phenomenon. Learners are expected to discover a pattern or rule that explains the phenomenon (hypothesize), and then to verify their hypothesis by interpreting visual (graphical) feedback. For example, in our Calculus course students were asked to observe an animated tangent line moving along a graph of a given function, and then to predict the shape of the graph of the derivative of the given function. Then, a simple modification caused the animation to rerun with the addition of a plot of a graph of the derivative function, thus providing immediate feedback for the student's prediction. After a few tries some students discovered the true nature of the relationship between a function and its derivative, in fact gaining a more general mathematical thought process as well.

In face-to-face classrooms the teacher explains such a relationship, but students rarely discover it in this deeper manner. However, teachers obtain feedback from classroom discussion and non-verbal messages students send, aiding teacher assessment of the depth of conceptual understanding the students have attained. In response to such feedback the teacher can modify instruction immediately. In a computer-mediated environment, where students interact with a computer simulation, the teacher does not get this same feedback.

On the surface it appears that the use of simulations, with visual feedback, enhances student understanding at the expense of feedback for the teacher. However, the situation is more complex. The use of simulations to facilitate learning complex concepts imposes demands on learners not encountered previously in face-to-face settings. First, some students may lack even basic computer skills necessary for learning in a computer-mediated environment. While the number of such students is rapidly decreasing, any such students may actually find that this context hinders rather than facilitates learning. Second, many students may have developed a rigid method of monitoring their own understanding in a subject, and thus may not value feedback that is delivered through the computer interface (Dedic, Rosenfield, Cooper, & Fuchs, 2001). Finally, the ability of students to interpret complex visual messages is often limited. Our work highlighted two ways of helping students to understand such feedback: deliver visual messages in stages, with initial messages being visually simple, and layers of complexity gradually added; and, augment visual feedback with elaborative textual feedback (Alalouf, Klasa, Dedic, & Rosenfield, 2002).

Providing feedback to teachers is a problem in computer-mediated environments for two reasons: the teacher does not obtain such information directly from students, and modifications to the environment require preparation time, therefore resulting in a delay in teachers' responses to any feedback that is obtained. We found that both students' answers to pop-up quizzes, and perusal of student activity log files can generate the requisite teacher feedback. Our research demonstrates that students' answers on pop-up quizzes correlate with achievement after the activity, thus feedback in the form of answers to pop-up quizzes allow us to predict how students are developing conceptual understanding. Further, access to log files allows teachers to trace students' activities during the use of simulations. However, both of these mediums for obtaining feedback must be built into the environment (e.g., Winne, 1989).

Feedback and Web-Based Discussion Boards

CMC tools, such as web-based discussion boards, are increasingly being used in distance education courses or as a supplement to traditional face-to-face classroom teaching and learning, especially in social science courses. One common usage of discussion boards is to enable group/class discussions on topics and issues related to the course. This asynchronous communication provides students with opportunities to reflect and respond to each other thoughtfully. Another effective use of discussion boards is for teachers to provide public and elaborate feedback to either an individual student, or the whole class, so as to benefit more students. For example, in group/class discussions, the instructor can monitor discussions and provide feedback when misconceptions arise. In our social science classes we also used discussion boards to provide detailed feedback on each individual or group project, and to encourage all students to read and comment on the work of others, as well as reading the instructor's feedback. Thus, students not only learned from each other, but also developed a better perception of their learning gap, and consequently helped make feedback effective.

Few studies have been conducted to document how, using CMC, peer feedback between and among students working on different projects can be structured successfully. The primary concern has been that learners are unable to provide each other with quality feedback (Latham, 1997). Our work in a graduate course in instructional design and an undergraduate course in educational technology integration, however, indicates that if appropriate structures and guidance are provided, peer feedback during project-based learning can be beneficial to both the provider and the receiver of the feedback. The strategies used to provide guidance, modeling, and scaffolding in the two courses using class discussion board and group spaces on Blackboard (2000) included: instructor modeling during the early part of the course; the provision of evaluation rubrics; and, the development of common criteria for best projects. In the midterm and end of course evaluations students responded very positively to the structured peer feedback approaches used in the class. Peer feedback placed students in the position of providing feedback, not just receiving it. This promoted student meta-cognitive and critical thinking skills and helped students develop multiple perspectives, thereby increasing achievement motivation and improving self-regulation in learning.

Conclusion

At the core of this paper lies our model of effective feedback involving interlocked feedback loops, portraying learners and teachers/peers as actors who both provide and receive feedback. The model, based on constructivist learning theory and self-regulated learning, emphasizes the importance of gathering learners' process and performance data, and providing feedback during the learning activities so that learners will be effectively guided toward achieving their desired learning goals.

Our findings concerning feedback in science and social science classes indicate that e-learning settings offer the opportunity to enhance feedback during the learning process so that student learning outcomes and affect are improved. However, it is important to note that effective feedback structures are not automatically a part of interactive simulations, CMC or other e-learning settings, and that teachers must actively design them in, and recursively continue to refine them through experimentation.

The Development of a Web-Based Continuing Education Course for Camp Nurses

Jo Lynne Lundy, RN, M.S. Ed.
Doctoral Candidate
Nova Southeastern University
USA
lundyjo@nova.edu

Abstract: Camp nursing is a growing area of specialized nursing practice and there are very few continuing education courses available to the nurse preparing to assume the camp nurse role. Approximately 10,000 camps are currently in operation in the United States and nurses are the most common healthcare providers for those camps. Camp nurses cannot rely on traditional medical equipment and supplies; they must use their own skills, clinical knowledge, critical thinking and problem-solving abilities to make independent decisions and nursing interventions. This research study focused on the collection of data in order to design, implement, and evaluate a Web-based continuing education course for camp nurses. The goals of this study were to determine if camp nurses are receiving specific educational interventions and role orientation prior to assuming camp nursing duties, and to use that information to develop a Web-based course that would enable nurses to bridge the gap between what they know and what they need to know in order to function effectively in the camp nursing role.

Introduction

Nursing is a dynamic process with the opportunity to practice in a variety of clinical settings. The traditional hospital-based practice is the most common, but there are many areas of practice that require specialized education. Camp nursing is one nursing specialty that is experiencing rapid growth. The American Camping Association (ACA) estimates that approximately 10,000 camps are currently in operation in the United States, and an estimated 9 million youth attend camps annually (ACA, 2001). Each accredited camp is required to have a healthcare provider on the property when campers are present, and this provider is most often a registered nurse.

Most nurses are unfamiliar with the outdoor milieu and must learn to adapt clinical skills and patient care to the camp setting. Camp nurses cannot rely on traditional medical equipment and supplies; they must use their own skills, clinical knowledge, critical thinking and problem-solving abilities to make independent decisions and nursing interventions. Due to varying geographical locations, local cultures and customs, and differences in communities, each camp presents unique nursing challenges (Erceg & Pravda, 2001). The nurse working in a camping environment must be prepared to deal with illnesses and injuries in the prehospital setting, and must be adequately trained to handle emergencies of all types.

Two key elements of camp nursing practice are a specialized educational program and a role orientation that will prepare the nurse to practice independently and competently in that specific nursing role. Without a standardized approach to camp nurse education, there can be no consistent standard of outcomes in clinical decision-making, and ultimately in the quality of patient care (Goodman, 1997). The Association of Camp Nurses (ACN) has published *The Scope and Standards of Camp Nursing Practice* (ACN, 2002), but there are presently no national educational standards or standardized courses to prepare nurses to function in this clinical environment.

Nurses enter the camp healthcare environment with a wide variety of backgrounds and experiences. Most nurses practice alone at camp, and without specialized education and role orientation, nurses assuming the role of the primary health care provider in a camp setting do not possess the knowledge base to be successful in that role. An educational course for entry-level camp nurses should include these essential elements: specifying the role and work setting, identifying competencies required to care for specific illnesses and injuries, writing performance criteria, implementing educational programs, and developing evaluation methods to determine when the performance criteria have been met (Alspach, 1990). Two other factors important to the success of a camp nursing course are planning and implementing the program effectively, and selecting an appropriate instructional delivery method (Phelps, 1996).

Goals and Research Questions

Very little has been written in professional nursing literature regarding educational courses for camp nurses. The few references to this topic tend to be standard-setting statements by camping organizations or "how-to" reports from camp nurses themselves. Camp nurses are usually hired for the position without ever having seen the camp and with just a phone interview with a camp administrator. It would seem appropriate for camp administrators to hire only the most experienced nursing candidates, but this may not be a viable option. Employment of experienced nurses in the camp setting may be difficult due to nursing salary expectations that camps are unable to meet, expanded autonomous role challenges that may be beyond the nurse's scope of practice, and the anxiety associated with increased patient acuity in a nontraditional nursing environment (Author).

Nurses seeking to practice in the camp environment should have access to a course designed specifically for the camp nurse, and an orientation to camp nursing practice prior to assuming that role, that is sufficient to enable them to practice safely (Maheady, 1991). This may be difficult because traditional nursing courses and orientation programs are usually not available in the camp clinical setting. Most camp nurses have to accept on-the-job training and orientation to the new role. Nurses in this situation must be accountable for self-assessment of their knowledge and skills deficits and for using self-study mechanisms in order to meet established practice standards. Before any deficit of knowledge, skills, and attitudes can be identified, it is essential to know which of these are necessary in order to deliver a high quality of care (Lindner, 1998).

The goals of this study were to determine if camp nurses are receiving specific educational interventions and role orientation prior to assuming camp nursing duties, and to use that information to develop a Web-based course that will enable nurses to bridge the gap between what they know and what they need to know in order to function effectively in the camp nursing role. This study attempted to answer the following research questions:

1. Are entry-level camp nurses being prepared for the camp nursing role?
2. How are camp nurses preparing for the role of camp nurse?
3. What is the essential course content for a Web-based course for the entry-level camp nurse?
4. How can the effectiveness of a Web-based course for the entry-level camp nurse be evaluated?

Methodology

A descriptive survey design was utilized for this study. The executive committee of the Association of Camp Nurses reviewed and approved this project, and the roster of membership of the ACN was provided as the study sample (n=346). The sample possessed the characteristics and qualifications from which the required data could be obtained, and was representative of the target population. Due to a lack of literature and research on camp nursing, no previously existing instrument was available, and no existing nursing instrument was suitable for adaptation. The survey questionnaire *Camp Nursing: A National Survey* was developed using currently available nursing literature and professional standards for camp nurses published by the ACN. In order to answer the research questions proposed in this study, the survey topics included camp nurse demographics, characteristics of camp health centers, camp nurse job descriptions, the process for and content of camp nurse orientation, and the evaluation of camp nurse orientation outcomes.

Prototype Web-Based Course

The inflexible nature of nursing practice and rapidly changing healthcare reform present challenges to camp nurse education; traditional classroom options do not usually meet the needs of camp nurses. The World Wide Web (the Web) offers many opportunities to deliver quality basic and continuing education; however, barriers to Web-based delivery of an educational course for camp nurses include access to the course from a remote camp setting (not all camps have computers or Internet access available), financial resources of the camp and the camp nurse, obtaining the resources and expertise to build and implement the course, maintaining technical support, and Web hosting issues such as security, sufficient storage space, and knowledgeable system administration (Horton, 2000).

A prototype course was designed using the data collected from the review of literature and the content portion of the survey. The course was delivered via the *Blackboard* course creation Web site (www.blackboard.com). The data obtained from the content section of the survey was used to determine the content that was included in the camp nurse course. A pilot course was developed offering three *modules of instruction*; the three content topics receiving the highest percentage of response in the survey were included in the prototype course: role of the camp nurse (94.8%), asthma management (93.6%), and management of routine illnesses and injuries (91.8%). Evaluation of the prototype course was performed by six camp nurse evaluators from various disciplines; they were given user names, passwords, and the instructions required to access the course.

Findings

The data analysis revealed that full time camp nurses and seasonal camp nurses did not have statistically significant differences in their responses to the content portion of the survey; both groups of nurses generally agreed that the topics queried were important, although the full-time nurses appear to agree more strongly. Both groups felt camp issues were more important than medical knowledge, although nurses who were not full-time camp nurses appear to feel more strongly about this. The mean number of years of nursing experience of the respondents was 21.3. The mean number of years of camp nursing experience of the respondents was 8.5. Only 22.7% of those responding had taken an online course prior to completing the survey, but 98% of those who had taken an online course indicated that they would take another online course in the future. 56.8% of camp nurses reported that they did receive some type of orientation; however, this orientation was described as including as little as a camp tour, to a one-week comprehensive orientation. Methods utilized by nurses in preparing for the camp nurse role include reading the camp policy and procedure manual (78%,)reviewing nursing and medical textbooks (48%), reading journal articles (49.1%), and taking a tour of the camp (49.0%). 82.8% of camp nurses received only on-the-job training for the camp nurse role.

Conclusions

The findings suggest that camp nurses are utilizing self-directed learning methods in order to prepare themselves for the camp nursing role. The survey results indicated that camp nurses prefer for initial and annual updates to be accomplished via face-to-face workshops/seminars, Association of Camp Nurses conference presentations/standards, and reviewing textbook information. Online courses were identified as being important for annual continuing education updates, but most of the respondents preferred face-to-face continuing education offerings for initial preparation.

Until there are educational courses specifically designed for camp nurses, this population should continue to use self-directed study methods to prepare for the camp nurse role. Each camp has unique medical, geographical, and cultural concerns, and the camp nurse must be prepared to care for that specific camper population. The nursing profession is based on human contact and many of the respondents indicated that the preferred delivery method for continuing education offerings is in the traditional face-to-face setting. However, those respondents who were more comfortable with computer skills indicated a preference for online continuing education.

Abstract

E-learning seems to suffer from the heritage of many "e" things that in the last decade formulate the new business environment. The overestimation of the role of technology causes a misunderstanding concerning the key issues in e learning (Lytras and Pouloudi 2001). Our approach for e-learning recognizes three dimensions as the critical pillars that have a direct impact in e-learning performance: E-learning pedagogy (Lytras and Doukidis 2001), (Lytras and Doukidis 2000) , knowledge management (Lytras and Doukidis 2000), (Lytras, Pouloudi et al. 2002), (Lytras, Pouloudi et al. 2002) and Application Integration. This paper focuses on E-learning pedagogy. Our intention is to provide a thoroughly analysis of parameters that justify a pedagogical strategy for e-leanring exploitation. The ultimate objective is to investigate the role of specific learning process in the exploitation of learning content and in the support of dynamic unique learning experiences.

1. Introduction

The case of human resources management in business environments is of vital importance for the establishment of business strategy (Carter and Scarbrough 2001). Knowledge exploitation and learning capability (Ryan 1995), seem to be two integrated aspects of the same phenomenon: The establishment of continuous improvement flexible mechanisms for the exploitation of the intellectual capital in business and academics environments (Coulson 2000). In this context where the investigation of the performance of the undertaken effort is of critical importance for the justification of investments, the detailed analysis of success factors in e-learning is of critical importance.The Multidimensional Dynamic E-learning Model (MDL model) (Lytras and Doukidis 2000), (Lytras and Odman 2001), summarizes a hypothesis, that in e-learning the overall performance can be overviewed in the mass of a cube which boundaries are determined by three parameters. The e-learning pedagogy dimension, the Knowledge Management sophistication and the application integration dimension.

The Multidimensional Dynamic e-Learning (MDL) Model is based on three complementary dimensions:⊡ The Knowledge Management dimension ⊡ The e-Learning dimension ⊡ The application integration dimension. Each of these describe in synopsis detailed considerations that confront the ecooperation platforms such as knowledge management systems with embedded e-learning pedagogy and capacity of dynamic integration with other crucial business applications. To be more specific we will use three explanations for the three dimensions of MDL model. The **Knowledge Management Sophistication** summarizes the ability of the e-learning platform to manage learning content in various formats, to re-use learning modules and to support knowledge management processes such as knowledge creation, knowledge codification, knowledge transformation and knowledge diffusion. The **E-Learning Dimension** stands for the ability of an e-learning system to construct effective learning mechanisms and learning processes that support the achievement of different educational goals. With no doubt this dimension incorporates issues like learning styles, learning needs, learning templates as well as learning specification settings. The **Application Integration Dimension** summarizes for the e-learning platforms the capacity of collaboration with other business applications in order to obtain learning content from real business operations. This dimension seems to be the less detected on the common platforms and this causes a number of gaps for the effective implementation of cooperation systems. The critical issue of insufficient content in many situations is due to the inability of the organizations to establish a knowledge generation mechanism through the operation of information systems that support the most important business processes. Our paper is trying to explain further the e-learning pedagogy dimension. The detailed analysis of each dimension formulates an analytical tool where the delivered value in an e-learning collaboration can be represented in the surface of the cube.

2. Describing methods for Learning Value classification

One of the major obstacles in e-learning is the static approaches to the delivery of learning content. If we assume that in an e-learning system we can obtain sufficient content then the key question is how do you diffuse it to learners and how can we establish effective motivation mechanisms?

For this purpose we decided to analyze the propositions of well-known researchers such as (Bloom and Krathwohl 1984), (Shuell 1992). The key idea of their work seems to has a direct impact in every implementation that refers to learning. But let start our syllogism concerning their relevance of their propositions in learning. The traditional approach in e-learning is mainly focused on the development of session and their delivery through internet usually through a Learning Management System. Unfortunately these platforms do not prove their learning capability. A hypothesis whenever we refer to information systems is that the users of systems require the fulfillment of several needs and potentially this fulfillment is based on a value realization. In other words transforming this general statement in e-learning context we can claim that an e-learner demands the reveal of value components when he/she interacts with the e-learning system. This value realization can be investigated in different level: Technology, content, functionalities, processes, communication etc. But irrelevant of the level, the key

BEST COPY AVAILABLE

understanding is that e-learning is mainly a learning phenomenon. From this perspective the value that the engagement of information and communication technologies promote in e-learning has primarily to be realized through the learning sophistication of the whole system. The cataloguing of learning objects in a database (which is several packages such as WebCT is not as simple) does not mean that learning is guaranteed.

The main this of the e-learning is the specification of engagement mechanisms with the learning content. If we establish capabilities that will set an environment where learners feel motivated and are engaged in learning content exploration then their perception of value is increased. In this direction three concepts are core [illegible] detail analysis: Namely educational objectives, learning processes and learning functions.

2.1 Bloom's & Shuell' s Approaches

The limited space of this paper do not give as the opportunity to discuss in detail two approaches that have for many supported the educational design. The development of a classification framework for writing educational objectives was the main contribution of Bllom in three domains Cognitive, Affective and Psychomotor. Especially in the cognitive domain the hierarchy opf educational goals incorporates: **Knowledge, Comprehension , Application , Analysis , Synthesis.** The taxonomy is hierarchical in the meaning that levels increase in difficulty and sophistication as well as cumulative since each level is based on previous levels or it assumes them as cornerstones in a step b step process that promotes the achievement of well defined objectives. Additionally the 6 levels can be used as an investigation basis, which promotes the learning performance and the highest possible degree of learning content exploitation. Especially in an e-learning environment a such starting point is very crucial. The dispersed learning objects can be packaged using a value adding proposition through learning processes with specific life cycles overstepping the uncertain learning outcomes in the traditional approach where a hierarchical structure of linked modules sets a static learning scenario. The combination of different learning processes and the justified enrichment with metadat a of the various learning objects in order to support different learning processes seems to be an effective knowledge and learning management mechanism. . More over if we accept this scalable qualitative distinction of learning processes then we can un derstand why the attachment of metadata admit personalized learning since each learner could exploit learning objects in the basis of the selection of specific learning processes. The cognitive level of learners in this way, becomes the value driver for increased learning performance. Shuell identified a set of psychological processes, such as raising attention, expectations and motivation, activating prior knowledge and perform monitoring, that foster effective learning in the student. The perception of the learning function as "*an attribute of the learning material in a specific context*" is highlighting the purpose of our research in e-learning. If we can justify several learning processes that are based on the research findings of Bloom and Shuell then t he context for the exploitation of the learning content is secured. In this case for each piece of learning material the author or the knowledge provider has to state the learning processes it serves for the various learners. The list of the 12 learning fnctions determined by Shuell is: Expectations, Motivation, Prior knowledge activation, Attention, Encoding, Comparison, Hypothesis Generation, Repetition, Feedback, Evaluation, Monitoring, Combination, Integration, Synthesis

2.2 The MDL value proposition for e-learning pedagogy

The contributions of Shuell & Bloom propositions facilitate our research. The integration of their approaches can provide a value-oriented approach concerning the delivery of learning content. The distinction of different educational goals and learning functions that promote a goal-oriented delivery of content promotes a dynamic parameterization in an e-learning environment. The dual concern of Shuell model, the fact that the specified learning functions can be utilized both by learners or educators influences and our approach: In an e-learning environment the content is provided by authors and is exploited by learners. But the packaging mechanism of content has to based in metadata that promote the dynamic nature of learning content exploitation. If we try to integrate the main ideas that underlie in the two approaches (Bloom, Shuell) , then we have to admit that there is a qualitative distinction of learning performance which is promoted through specific functions or processes that prerequisite different cognitive skills and promote different value to learners. From this perspective the key issue of how to organize and package the learning content and how to engage learners in an e-learning environment can be derive sophistication through the establishment of dynamic learning processes. The combination of learning processes that have specific life cycle set the context for learning scenarios. The advantages of this approach is that if we specify metadata that support more than one learning process then this increases the exploitation capabilities of a learning object and promote a personalized learning environment. In our model can be added more learning processes if we model them. The underlying logic is that the learning object is packaged through its adaptability to the context of specific learning processes. In our research approach we have investigate 9 learning processes (Lytras, Pouloudi et al. 2002) , and we propose them as the basic value carrier in e-learning environments. These learning processes do not demand a magisterial role but set a base for further exploitation. Namely these learning processes are: **Presentation, Analysis, Synthesis, Evaluation, Reasoning, Explanation, Relation, Problem Solving, Cdlaboration.**

3. Detailed presentation of the proposed e-learning Pedagogy scaling

Our basic syllogism is that e-learning performance is directly related to learning processes, which are value carriers for the learners. The first implication is the requirement to model each learningprocess and consequently to specify metadata for each process in order the linguistic concept of learning process to get empower from descriptive information that can be promoted to learners using ICTs. The ultimate objective is the understanding that reusability of learning resources is not panacea not even a promise for higher learning value except a number of metadata justifies the reusability in terms of diffused value.

An initial statement is that the value in each process is not objective but subjective since each learner pays different importance to processes according to his cognitive level and previous experiences. More over the life cycle of each process has to be analyzed from the perspective of learners and authors. The distinction of several phases does not assume a sequential flow of tasks but rather an indissoluble whole of engaged parts. In the next pages are presented through tabular synopsis the life cycles and the implications of Shuell and Bloom's work in our research.

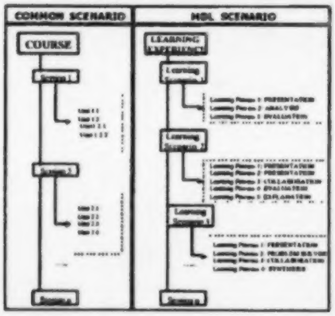

Figure 1. The proposed revision in e -learning content delivery method through value adding learning processes

4. Conclusions

Our approach is setting a context for further exploitation. With no doubt the current situation in e-learning market does not represent the fascinating issue of the incorporation of information and communication technologies in education. Many people use the e-learning term and presuppose the presence of a PowerPoint presentation accompanied with audio as the technological infrastructure for e-learning realization. The MDL framework is being evaluated for more than two year and the findings are very promising. The achievement of higher student satisfaction is only one of the key findings. Finally we have to say that this model is also very demanding. It's realization requires a lot more efforts from both academics and knowledge providers that seem to forget the nature of learning when they prepare learning material. Community Action/interaction Management System

(A Course/Group Management System that Fosters Community)

By Brian G. Mackie
OMIS Department
Northern Illinois University
USA

Norbert Ziemer
OMIS Department
Northern Illinois University
USA

Abstract: Most course/group management systems are designed from the perspective of the facilitator or the administrator. Since these systems have been developed with an emphasis on administration, student ease of use and student-to-student interaction is frequently an afterthought instead of a design requirement. A student-centric course/group management system (CAMS) has been developed, in order to improve learning outcomes. This system allows participants to interact with one another, and makes the interaction process user-friendly. It is intended to help participants become acquainted with their cohorts quickly, whether the course is on-line or web-enhanced. The core of the system is a fully developed database. The software is open-source, requires minimal configuration and is currently being beta-tested with web-enhanced courses, fully online courses and online community groups.

Background Info/Impetus

Many Northern Illinois University faculty had previously used other commercially available class management systems such as WebCT and Blackboard. Observations by faculty members and student feedback from those learning experiences were used as a basis for the CAMS project. Certain learning challenges were found to be more prominent within an online or web-enhanced learning experience. One problem was the fact that the human elements and visual cues from a face-to-face experience were all but eliminated. Another problem encountered was the ease of navigation and use for both the participants and the facilitators. It was noted that there were times when a user was required to make seven or more mouse clicks to navigate to the desired feature or link. Faculty also experienced system drawbacks, such as the inability to efficiently transfer files from other applications and the limited level of customization allowed.

Deficiencies found with Current Systems

Human elements

The human element deficiencies are crucial to the success of an online learning platform, since the first impression when a participant enters the system can be a lasting one. The online learning environment, by definition, utilizes a different learning environment. This interface can offer advantages over a more traditional face-to-face format, but also has drawbacks including the lack of visual cues (Salmon 2000). The environment may feel less "warm" and welcoming to the participant, since frequently he or she cannot see or hear the facilitator and/or other participants. The inability to associate a name including phonetic pronunciation with a face has been a disadvantage of online Course Management Systems (CMS) compared to face-to-face learning environments. Another deficiency is that participants feel isolated or disconnected within the online learning environment. These deficiencies must be addressed by any viable CMS as they strongly influence student retention and learning outcomes.

Navigation, Learning Curve, Ease of Use

Many of the systems evaluated have lacked easy and consistent navigation and interaction. Systems can become so complex that a participant may be required to navigate through seven or more screens to locate/access a desired feature. Navigation deficiencies can slow down the learning curve and possibly become a deterent to the participant.

Flexibility/Customization

A drawback to many other CMS applications is the restricted movement of data. Either the inability to incorporate data from other sources into the system or export data to other sources are limitations caused by not being able to easily access and reuse information within the system. These limitations are major deficiencies of many CMS applications.

CAMS System Components Addressing These Deficiencies

When participants log onto the system, they are presented with a course/group selection page. Beginning with this page the individual's picture is displayed and they are immediately drawn into the community. Upon course/group selection, the participant is transferred to the main course page. Salmon notes that it is important for participants to contribute. The main course page (see figure 3) contains the following information and links to information that the student can **update**:

- Picture of each student in the class
- Phonetic spelling of student's name
- e-Mail address
- Personal website link
- Bookmarks link
- Book exchange Link

The system includes additional components, accessible from the main course page:

- Faculty picture and Faculty comments
- Most recent Class Announcement and a link to all announcements
- Class Information including Office Hours, Book information and Syllabus
- Class Notes link
- Class Assignments link
- Discussion board link (with pictures displayed on discussion board)
- Chat link (the chat program attaches the participant' picture to his or her message as it is sent) see Figure 1
- Display grades link (complete grading program/grade book) with input/export capability see figure 2

Brian, the following are your grades for Class_managment_sum02-1 up to 8/20/2002

Assignment

Assignment title	Grade	Max Pts	Comments	
Sample assignment	Not Graded *	10	test	
Assignment totals	0	0		
Percent				n/a

Quiz

title	Grade	Max Pts	Comments	
test1	22	22	help	
Percent				100%

Overall Totals	22	22	
Percent			100%
weighted avg			100%

* Note: An assignment that says 'Not Graded' is not included in either total points earned or total points possible

Figure 2

The grading program allows the faculty to enter grade types such as quiz, test and project scores. The system is designed to allow weighted grades, so each area can be given a different weight. The faculty creates an assignment and posts a complete assignment description for student viewing. There is also a provision for the facilitator to enter comments for any student grade. There are two comments for each grade; one is available the student, the other is not. When working with student grades the students' pictures are visible. In addition, from the Class main page the students are able to view their scores to date for the class.

2002

CLASS_MANAGMENT_SUM02-1 Class Directory

Figure 3

It was decided that the course/group management program would minimize the number of page visits required to reach a desired feature. It was also decided that users should not need a large amount of training to access and use CAMS. Where possible, all selections, modifications and/or additions would use the same techniques. Therefore, all information is updatable whether by participant or facilitator through simple web page forms. The participant or facilitator can update the information using html tags to

BEST COPY AVAILABLE

produce exact formatting; or they may opt to enter the data as text with carriage returns and spaces. If entered in the latter format the system will automatically maintain the format. Participants are allowed to add and update both their personal information and bookmark categories of interest. Additionally, they are allowed to create bookmarks for the class including comments for each bookmark. This is another way of keeping the participant engaged.

Current Status

The CAMS application has been through two levels of beta testing, in both web-enhanced and fully online courses. A community group of approximately 130 OMIS department graduate students is currently being tested. It is anticipated that the CAMS application will be used by many courses in at least two colleges at Northern Illinois University and several other locations.

We are currently monitoring system performance and researching facilitator/participant satisfaction with the system. The system is very robust and ready for expansion to other institutions.

Future Research

It is hoped that other institutions will recognize the potential of the community based and participant-centric system (CAMS) and will contact us to become part of this ongoing research.

Abstract: E-Learning has been viewed as technology enhanced and delivered learning in Australia for many years. By extracting the best of the traditional classroom experience and technological infrastructure we could lead to an integrated learning called Blended Learning. Education have became globally accessible; the Blended Learning now needs number of enhanced collaboration features in terms of pedagogical instructions that sets it apart from those existing e-Learning opportunities. This paper explores some of the educational issues underpinning the possible uses of CeNTIE's high broadband network and Telecollaboration software being under development at UTS on an exploratory basis. This paper argues that the e-Learning in the Australian higher education sector is best conceptualized as a collaborative process with educational outcome measurement and the technology (media) does influence the learning provided the participants create their confidence in the use of underlying technology.

Introduction

" E-Learning describes the way new information and communication technologies (ICT) are set to re-invent education and learning in a digital world. In short, it means Internet enabled learning: an exciting range of opportunities for educators and learners alike to use new skills and tools to prosper in an information society" (Arthur Anderson, 2000). Australian universities have undergone profound changes over many years in terms of their commitments to provide quality e-Learning opportunities to their students. In recent years e-Learning has been an integral part of wider use of University's teaching and learning practices and policies. For instance, although most Tele-teaching lectures in the past proceeded smoothly, there were issues like connection problems, time delays in transmission of material and interaction among the participants in the lecture. When it comes to e-Learning, the **REAL** learning is in **LEARNING** *not* in "e" (Russell Thea, 2001). The research at Monash University, Melbourne reveals that apart from the disadvantages such as reduction in learning time, increased potential for disruptive student behavior and reduction in access to lectures, students at remote sites did not feel part of the lecture and have experienced a reduced concentration span. The investigators also found that there appeared to be always weakest interaction between learners compared to content-learner interaction and instructor-learner interaction. They also pinpointed the areas that needed particular attentions are improvement of staff tele-teaching skills and technology (Abdel Halabi, Juhani Tuovinen & Jodie Maxfield, 2000). The advances in digital networks have now leaded us to the creation of new and innovative telecollaboration environments worldwide. Today there are numerous telecollaboration software tools that have helped the educators to broadened their base and allowed them as facilitators, to innovate and customize new education models to implement their new ways of teaching and learning activities. CSIRO's Centre for Networking Technologies for the Information Economy (CeNTIE) and recently received funding from the Australian government and industry collaborators to build a next generation research network linking the key research institutions in Australia is in progress. It recently completed the first metropolitan trial of 10 Gb/s Ethernet network in the Asia pacific region demonstrating shared virtual environments running a surgical training system. The CSIRO is working with the psychologists and educators from three Australian Universities including University of Technology, Sydney (UTS) to identify the appropriate uses in higher education for this high-capacity broadband network system. By embracing a new telecollaboration environment in Australia's higher education sector, UTS is hoping to challenge both the educators and technologists to adapt themselves in a situation to oversee this unpredictable surge of constantly challenging innovation.

Why Collaboration beyond Lecturing?

A common base of all collaboration is Learning. Task oriented collaboration involves the ***back grounded learning*** and the collaborative (peer) learning involves both the tasks as well as the ***fore grounded learning.*** Recalling Vygotsky's theory of social constructivism, where students construct knowledge based on interactions with others, it is evident that telecollaboration helps the participants to work together (interact) on a common, shared goal despite of their physical separation. There are five structures for learning that may or may not occur in a traditional classroom scenario. For instance, use of facilities such as information banks, construction kits and the task managers. (Salomon, G., Perkins, D., & Globerson, T, 1991). Collaboration beyond "lecturing" means designing interactive collaborative learning experiences for all the participants involved and facilitating them throughout their learning processes through those experiences (engagement theory). In which case students would be expected to play their role not just as passive observer but an active constructor of knowledge by taking responsibility of their own learning (out-of-box thinking). "Rich environments for active learning" or REALs are constructivist based and designed to encourage student responsibility and motivation (Dunlap & Grabinger, 1996). Now we have reached into a stage of collaborators sharing the application or white boarding apart from involving synchronous and/or asynchronous communication through audio, video, and/or text and reviewing their course material both synchronously as well as asynchronously. Our research on reviewing numerous collaborative models and theoretical frameworks, shows that currently, there is no one system that plugs the user into the remote site where an individual can perform complex group tasks and feel the sense of presence and contribution with the help of set of collaboration tools and utilities that they may choose to use according to their personal preferences and work patterns (student centred learning). Some of the important collaboration service elements been described in our mock up, helped us to visualize our ideas like joining and leaving a session, pointing to shared objects and communication between many-to-many users (reflective conversations).

According to the Workshop on New Visions for Large-Scale Networks: Research and Applications held in Vienna, Virginia, 2001, collaborative environments need to support transparent, intuitive human interactions with services such as automatic configuration, ubiquitous access, security, multimedia capabilities, immersive environments, expert consultation, and side conversations by providing proactive, intelligent, dynamic and "natural" interactions among the participants. It also says the future collaboration environments will need to deal with unpredictable and emergent changes, meet hard real-time constraints, and handle asynchronous events as they occur. This involves a clear understanding of all the participants involved in the collaboration processes to know the need for collaboration (Dale Spender & Fiona Stewart, 2002). Identification of telecollaborative strategies by the facilitator of future telecollaboration session would maximize the learning opportunities of all the participants involved. This is well matched with the vision of our telecollaboration project at UTS.

Does technology (media) influence the learning?

Technology always has been a strategic investment in the higher education sector to validate its missions. Though the technology plays a major role in driving the revolutionary changes, the challenge for the educators to keep pace with those changes still remains the same. To challenge the traditional teaching paradigms, the technology (media) needs to play a major role. These are the two areas of "islands of innovation" due to many different constraints. The development of digital networks now justifies the need for further emergence of development, maintenance and calibration of those options been identified by those areas as pathfinders of our future telecollaboration session. Online education makes it very rich information medium, not simply because of the multimedia capacity, but it is interactive. Online learning is not so much about taking in existing information, but connecting and creating new resources, actively assembling information and engaging in problem solving. This information in turn can be "checked out" by others. Technologies are not to be treated just to read or receive the information, but needs to be used and "repurposed". As all digitally connected individuals can make information, there are multiple voices, rather than one voice, so there is no one right answer but many possibilities (Dale Spender & Fiona Stewart, 2002). For example technology would enable us in rapidly describing or instantiating new shapes, performing simulation and animations of processes and illustrating the transitions. Encouraging the use of multiple modes of representation (different mediums) is one among the "seven pedagogical goals" of constructivist, learner-centered environments (Honebein, 1996). The technology has been always more powerful in terms of providing transmission and sharing of the content and encouraging more out-of-class student reflection. Our main aim is that the proposed technology would help our educators to make further focus shift from content to the contemporary approach (from surface level learning to deep level learning and from independence to interdependence). Some educationalists strongly believe that learning outcomes in the main are not affected by the technology. Some even view technology as a tool for decontextualized drill. But to others like researchers at UTS, technology is an opening door for creative expression and higher-order thinking skills. In all our debate, we rarely take the time to explore whether there are several ways that may effectively contribute to a good education (David D. Thornburg, 2002). It is sad that many educators until today have little understanding of the limitations and constraints of the technology they use. They need to realize the fact that with the proper understanding of use of technology the participants can perform well in a more easier and productive way. One of the critical concepts of Salomon's theory is that the effectiveness of a medium depends upon its match with the learner, the context and the task (Salomon, 1977).

There are just two remaining hurdles that have thus far prevented the widespread adoption of such a practice. The first hurdle is the multimedia interaction requires broadband networking that is economically accessible. Moreover, the resources of the network must be either in abundance or carefully controlled and used in real-time to ensure that the multimedia interaction is of sufficient quality to prevent the technology from becoming a hindrance to the collaboration. According to the e-Learning user survey been conducted in April 2001 at e-Learning conference & expo held at USA, 53% of the respondents said that the lack of bandwidth is the major challenge to the current eLearning techniques (For example, the problem of having unintelligible audio and jerky-motion video etc). Even with the supply of enormous bandwidth that CeNTIE would offer, we as both educators as well as technologists should know the accountability of its uses. One of the most important technical issues here is just by increasing the bandwidth we will not solve the multimedia burstiness problem. In increasing the bandwidth in distributed multimedia computing, the user acceptance of high degree of perceptible quality of multimedia data is always significant factor. The notion of quality of service (QOS) is central and still receives significant attention among the multimedia network researchers. This includes maximal or minimal resolution, the average throughput, allowed error rates and timing requirements etc. For instance research on real-time text editing and the task of distributed synchronization between multi media data could solve some of the problems of QoS requirements in a telecollaboration scenario.

The second major hurdle is the unavailability of set of software tools and utilities to support and enable our future collaborative interactions. The available ones found to be designed for specific contexts and thus, do not adapt well to other situations. Furthermore, many are constrained by capabilities that were available at the time of their design and implementation, but the rapidly changing ICT field has quickly rendered these obsolete. And finally, and probably most importantly, our collective understanding of collaborative processes and the interactions necessary to make them effective is in its infancy – so the design of software tools to enable, support and perhaps even enhance collaborative outcomes is ignorant of the basic requirements for such tools. The platform-independent software under development for the above purposes would allow integration of transmission and sharing of contents along with pedagogical instructions. By being very easy to use, proactive, and engaging it would provide some intelligence. For instance, the development of special tools such as color deficiency tool, sign language modeling etc would be very helpful for the disadvantaged students.

Today's e-Learning infrastructure is still immature in the tools to analyze and measure results to correlate them into your organization metrics (Bersin Josh, 2002). The purposes of intended outcomes in a telecollaboration scenario are never unchanged. The technology would force us to do certain new things or perhaps do things that we would otherwise not be able to do. Outcome based measurement is critical and time consuming. This is because of the reason that the range of possible outcomes that people in different context might want to achieve is very large. This arises the need of a highly adaptable, large spectrum of outcome measurement techniques that could be available to the range of possible outcomes.

Conclusion

Many factors such as difference in motivational factors, skills, pacing and concentration shifts of the participants that affect the e-Learning are areas of further study. The researchers at UTS are expected to deliver a product (technology), which involves numerous collaborative processes that would solve some of the existing educational problems. This project mainly aims at developing a set of high- engagement, high-performance and high- impact remote access tools, utilities and the appropriate technologies that would be capable of providing a flexible framework for active pedagogical teaching and learning approaches. There is a shared understanding among the researchers at UTS of how to build and use telecollaboration software that would encourage the educators to try new forms of teaching and learning and help them to learn how to utilize the latest technical possibilities. This includes identifying the factors to succeed in spite of the barriers created by this new exciting technology.

Talk and Chalk digital

Carmem Maia
Núcleo of Colective Inteligence applied to Education
Departament of Interactive Higher Education
University Anhembi Morumbi
Sao Paulo, Brasil
Carmem@anhembi.br

Abstract: Is e-learning a modern or, better, a digital version of the already traditional "talking...talking... and chalk" which we witness in the model classroom?

Are we not merely reproducing in a digital way the same traditional education models which are known to us, ignoring the means and possibilities of methodological and curricular innovation which interactive technologies allow?

Are we not repeating the same phenomenon which occurred during the early 80s with the emerging of Informatics laboratories - hermetically closed classrooms with a large number of aligned computers -, which in practice did nothing but copy the same model of lessons given in the classroom with traditional desks?

Introduction

Presently, Higher Education Institutions (IES) are being pressed to develop and use new communication and information technologies for Brazil's students as a way to improve or develop traditional higher teaching through quality. The fever of "e-learning", is now a "hype" that is invading the Brazilian higher education market, has compelled many "IES – Instituições de Ensino Superior" (Higher Education Institutions) to try and modernize their technical staff, ignoring their prime human resources (professors) and the main purpose of their business (teaching-training).

With the increasing technological progress of the tools for delivery of courses and disciplines, are we not running the risk of moving towards the mere digitalization and storing of information and contents, without, necessarily, in the majority of cases, preoccupying ourselves with, and taking major care of, those actors which are on both sides of this screen, that is, professors and pupils?

The question is: how must Higher Education Institutions prepare themselves; how must they focus the development of distant higher education interfaced by the interactive web communications, how can they win the challenges of an ever growing production of topics for an ever increasing number of students and yet have their mind focused on ROI in a way to preserve and maintain all efforts focused on the teaching-training process of the student and all the possibilities referring to innovation, curricular integration and cooperative working formation which available technologies and tools can offer.

How can we develop and implement courses and higher education projects at a distance with the proper tools but with distinct adequate characteristics, adapted to the methodologies and cultural features of each region, and allow professors to maintain their pedagogical and methodological identity even if focused on "mass" education, using one proper tool for the implementation of courses and disciplines?

The challenge is to keep e-learning focused on teaching-training, based on the development of truly cooperative and collaborative methods for an ever increasing number of students, including an integrated management of the topics involved, working efficiently and producing satisfactory proven results, from a pedagogical point of view as well as an institutional point of view.

What is going on

Recent decree 2253, institutionalized by the Ministry of Education and Culture, on 18th of October 2001, literally emphasizes the preoccupation of governmental organs with regard to increasing technological progress, of which higher education cannot be kept afar.

On the one hand, we have statistics about the number of outgoing pupils of higher education wanting to enter university and we know that something has to be done to facilitate the access to these universities.

On the other, we know that the traditional educational model of teaching leaves much to be desired from a qualitative point of view, mainly, in "mass" institutions, where very often more than 100 pupils are gathered in one classroom. What type of interactivity or relationship can exist between pupils and teachers in such a space and during the short time of a traditional lesson ? (50 minutes lesson means basically 30 minutes of real lesson, subtracting all delays by the teacher and pupils, starting the lesson, ending it, etc...). Besides, the model of curricular development of a graduation course, for example, also requires reformulation. To merely create a curriculum, disciplines and classes and wait for integration is not sufficient. The model for higher teaching we know of does not attend any more the pupil's formation requirements and professional performance, and should be reformulated, re-invented.

On the other hand, we have an avalanche of technologies and tools being developed and offered by the teaching institutions. Very often the IES are quite satisfied with the technological resources and automation of contents and do not dwell on the needs and necessities of teaching-training. Technologies should be a means of improving the training process, they should be considered as powerful tools for the necessity to re-invent higher education; however, technological resources are not enough, there should be an educational intelligence behind any system, a powerful brain knowing how to use technologies intelligently with a view to meeting training requirements; otherwise, we are just, and once more, repeating the old and antiquated model of the traditional "talk, talk...chalk" in the classroom, and what is worse, running the serious risk of potentializing - once we are on web and the web is a potentializer - a model which we already know is obsolete and does not meet any longer the requirements of pupils, teachers and the institutions themselves.

By means of decree 2253, legislation clearly shows that the path to follow revolves around a mix of what is being called Click and Brick, that is a mix of the factual presence and the virtual; however, to this end, the academic spheres of the IES (higher education institutions) should re-organize and orient themselves towards this new paradigm. This decree stimulates the use and implanting of technologies for improving this process, thus allowing institutions to provide 20% of the course or discipline duration, by way of distant education, through interactive communication technologies, which in practice means re-orienting educational course projects and teaching plans towards a new format satisfying the requisites of this mix.

The tools and technologies being developed strive to show that in the quest for productivity and attendance to an increasing number of beneficiaries, the relation between the cost of this benefit and the ROI must be taken into account when choosing a technological tool and to this intent, the institutions themselves should be aware of what their business and intelligence point at in relation to the development of the disciplines contents, thus leading to the improvement of training and knowledge and not merely to the development of a technology.

University Anhembi Morumbi e-learning Case

University Anhembi Morumbi is a private university located in the Southeast of Brazil, in Sao Paulo city. It has been founded 35 years ago, implementing the first Tourism Bachelor course in Brasil, and during all this decades, the University have been pioneers and innovative in the Higher Education System in Brasil, which is a very traditional academic system, very resistant to changes.

In the beginning of the 80's, the university begins the implementation of the Department of New Technologies in Education, created to think and implement new strategies and new methodologies, using or not technologies in education. This means the training of all the faculty staff in new technologies and researching during all this years the use of new possibilities to optimize the traditional methodology of the face to face classrooms.

In the 90's, with the advent of Internet, the University creates the Dept of Interactive Learning, to research the net interactive possibilities to Higher Education. During this last decade, many courses , short courses and pos graduation courses have been created and developed by this department, and the University have been recognized as one of the pioneers in the implementation of a successful "mix" between online learning and face to face classes. During the framing and implanting of on-line and interactive processes at Universidade Anhembi Morumbi, we opted to develop first of all favorable conditions for the improvement of teaching nearly 10 years ago, at a time when there were no virtual training environments or the present educational tools for the development of courses.

For about 5 or 6 years we worked on the research and development of this tool, the result being that we acquired the know-how and expertise in efficient methodologies related to distant training, which in turn led us towards the development of new courses and disciplinary contents not to be given by way of the traditional "talk..talk..chalk".

During the last two years, with the configuration of this new motion opening for the Institutions many other possibilities to improve our classes, we realize the necessity of a system that could manage more than 3000 sincroniusly, and we had to face a serious problem regarding management of the contents and small bugs in the system which cannot occur in large scale teaching.

The challenge now is and will be in the use of a teaching automated authoring tool, like Blackboard, highly efficient and with high quality distant education methodologies so as not to reproduce the traditional educational model requiring the student's presence. Once solved the problem of technological bugs, we shall have to pay attention to the development and training of human resources, integrated contents, know-how and virtual "animators" so that, although at a distance, students and teachers should feel motivated and stimulated to pursue their training and that we do not make poor use of the potentiality of human and technological resources.

Authoring Tools – A knife of two edges?

During this last two years we have been looking and researching for authoring tools which could help us to be more efficient and productive in the delivering and in the content production of the courses. We realized that our logistic system of production the e-learning courses were not efficient and It demands a tool which the teacher could manage the course content the way he wants to, with no technical assistance.

However, our concern was in do not create the same traditional model of the information delivery, now digitally, and one of the purpose for this is work with the teachers in a way that he or she could be a content manager, orienting the students to build their own knowledge and not just replyng the old paradigm of the traditional classroom.

The authoring tool, Blackboard, WebCT, Docent or any other, have two faces: Could be very useful and a helpful hand to be more productive and automatized, because they are very user-friendly and easy to learn, but in other way, this tools could be also a knife of two edges, which must be used very carefully, not only focusing the scalability and the managing of the students, but mainly in the process of learning that the student will be involved during the course.

Unfortunately, what we have been realizing during this research is that it is not easy changing cultures and changing minds, mainly the academic areas. Teachers are used with the face to face methodology and sometimes are not so receptive to chaging paradigms. The use of this authoring tools will create new roles for faculty, we believe that it will be very profitable for all: Institution, Faculty and students.

do not want to improve or There lies the big challenge of the new educational technologies and paradigms.

E-Learning for Distance Learners – Does it work?

John Chi-sang MAK
School of Business & Administration
The Open University of Hong Kong
Hong Kong (SAR), CHINA

email: jmak@ouhk.edu.hk

Abstract: This paper reports the use of Information Technology (IT) for enhancing distance learning in Hong Kong. The challenge of Lifelong Learning and the knowledge-based economy require us constantly upgrading and expanding our skills to meet the future, professional and workplace needs. A survey was conducted to investigate the impact of e-learning from distance learners' perspective, that aims at studying how distance learners might view their (1) course performance, (2) IT fear and anxiety, (3) feedbacks on e-tutoring, and (4) comments on course administration during the e-Learning process. Through a case study in the Open University of Hong Kong, this paper describes in details how an online course is designed, delivered and evaluated. The results indicate that with the opportunity for e-Learning distance learners can enjoy the online teaching and learning process. Although fear and anxiety are initially reported, they could be resolved and manageable during the course. Both tutoring and course administration could be improved through online technology.

Introduction

The Open University of Hong Kong (http://www.ouhk.edu.hk), formerly the Open Learning Institute of Hong Kong (OLI), was established by Government in June 1989, aiming to provide higher education opportunities for adults by open and distance education. OUHK offers more than 100 post-graduate, degree and sub-degree programmes in April 2002. The University recruited about 4500 new students in October 2001 and currently has about 26,800 students (OUHK, 2001a). The majority of them are aged between 22 and 35. On average, they take about nine credits per semester, equivalent to about half of the workload of a full-time student. The University uses a flexible credit system under which students earn credits for each course and accumulate credits towards a degree. Currently, most OUHK courses are print-based. There are also trained tutors who hold tutorial sessions, comment on and mark assignments, and answer students' queries by telephone and correspondence.

There is a vast amount of e-Learning initiatives currently taking place in Hong Kong, including PolyU's CyberU, HKU's SOUL, and CityU's iMBA. Many of the continuing education institutions are also claiming to offer e-learning programmes. However, the aims and objectives of 'e-learning' vary among the institutions. For simplicity, terms such as 'e-Learning' and 'online learning', 'e-course' and 'online course' are used interchangeably throughout this research. E-Learning can be viewed as a virtual classroom, incorporating a set of modern training tools, such as a study guide, notice board, student forum, online mentoring, and an interactive, multimedia courseware, e-library, which are aimed not only at the individual learners, but also at training institution. The virtual classroom provides many of the benefits of the traditional classroom while enjoying the major advantages of training delivered over the Internet that can be accessed at any time from any place. At many institutions, the effectiveness of e-Learning has not been well researched prior to its adoption. Daley et al. (2001) indicate that students' attitudes and perceptions of technology influence their ability to acquire and integrate knowledge, extend and refine knowledge, and use knowledge meaningfully. Understanding the factors affecting students' adoption of e-Learning should be a fertile area for research. Learners' willingness to adopt technology is of vital importance to the design and delivery of e-courses by distance education providers.

Research Questions

This study tries to better understand distance learners' attitude toward online teaching and learning. Also, the effectiveness of e-tutoring and course administration are being evaluated. It aims at studying (1) how distance learners might view their performance, (2) what fear and anxiety they may feel, (3) how they evaluate e-tutoring, and (4) how they evaluate online course administration.

Research Design

An IT-based e-courses with Web-based instruction design beginning in April 2002 was selected for evaluation. During the course, students received printed materials by ordinary mail and supplement online course activity and materials through a Web-based course server. An evaluation is then conducted to measure both the learners' perceptions and the effectiveness of course administration:

Subjects

An electronic version of the questionnaire contains 40 questions asking for quantitative information. The evaluation was conducted in July 2002. Seven hundreds and three adult distance learners enrol B121 course, which is running on-line throughout the semester. A total of 238 replies (33.86%) are collected and all of these responses were considered usable for this study after data validation and checking for excessive missing values. The average daily OLE user logins is 94.57 (11.63%) with average daily hits of 4823.23. The total user logins in June 2002 is 622 users (76.51%). Students connected to the OLE server in different ways: OUHK student dial-up kits (2.17%), OUHK Sub-nets (45.67%), and external Internet Service Providers (52.17%).

Method

A set of questionnaires on a study of how the online technology affects on students and tutors has been designed. The questionnaire is broken down into four brief sections, in which raw items have been developed reflective of (1) course performance, (2) computer fear and anxiety, (3) e-tutoring, and (4) online course coordination. The questionnaire used a 5-point Likert-type scale for each item (1=Strongly agree, 2=Agree, 3=Neutral, 4=Disagree, and 5=Strongly Disagree) to solicit students' feedback. The evaluation was conducted in mid-semesters of the course. Some of questions in the evaluations are based on the work of Zane Berg (1996) and Diehl (1989), whereas others are developed to meet the aims of the research. Details of the questionnaires are available upon request.

Course server

The online courses selected for the research include is B121 Business Computing with Internet Applications. It is a semester, 5-credit, and foundation-level course that comprise the Bachelor of Business Administration (BBA) degree programme. B121 aims to introduce learners to microcomputers and their applications in business; and enable them to develop, through hands-on experience, the knowledge and skills necessary to use common microcomputer software applications in business. Learners are required to make regular access to the Web-based course server via a dial-up modem or an Internet connection during their study. OUHK has developed a Web-based online delivery system, called the Online Learning Environment (OLE), to enhance e-learning experience. Based on WebCT 3.1.3, the OLE provides an interactive learning environment for communication among students, tutors and the Course Coordinator. The OLE is locating at URL: http://www.ouhk.edu.hk/ole, which consists of eight major students' components, including News, Administrative Information, Course Materials, Assignments, Interactive Tools, Personal Folder, Evaluation, and Help.

Major Findings

How students might view their performance in online courses (see Table 1.1)

Table 1.1 Issues	Frequent (%) (1=strongly agree, 5=strongly disagree)					Mean	Mode
	1	2	3	4	5		
Q1. Felt motivated to use IT in the learning process	18.5	55.5	23.1	2.9	0.0	2.11	2
Q2. Enjoy online learning via the OLE	12.7	38.8	40.9	7.2	0.4	2.44	3
Q3. Always read Course News	12.3	29.2	35.2	20.3	3.0	2.72	3
Q4. Like to work with classmates via online interaction	8.0	24.9	43.0	22.4	1.7	2.85	3
Q5. Read messages more than post messages	19.4	54.4	19.4	6.3	0.4	2.14	2
Q6. Perform better with group members online	6.7	26.1	53.4	12.6	1.3	2.76	3
Q7. Can better understand how the course was organised	22.9	46.6	22.5	7.6	0.4	2.16	2
Q8. Invest time to learn how to use IT	14.8	59.1	24.1	1.7	0.4	2.14	2
Q9. Perform well with the aid of IT	11.8	50.8	34.0	2.1	1.3	2.30	2
Q10. Felt much better prepared for the workforce	13.9	57.4	25.3	3.0	0.4	2.19	2

BEST COPY AVAILABLE

A great majority (74%) of respondents felt motivated to use IT in the learning process. They also agreed that the Internet could assist them in learning more about the subjects that interest them. As a result of learning how to use technology in the course(s), 71% of respondents were much better prepared for the workforce. With the course materials placed on line, 70% of respondents were able to more effectively understand how the course was organised. Reflecting on the experience, students (74%) thought the course(s) challenged them to invest time learning how to use technology benefited their study. It has been time well spent to learn how technology could be applied to their specific learning demands. All respondents were asked if their expectations of performing well with the aid of technology in the course(s) have been met. Here 63% of respondents indicated that it was, while less than 3.4% of respondents replied that it was not. One of the interesting findings is that 74% of respondents spelt more time to read messages from than post messages onto the Discussion Forum. They tend to receive than contribute to the e-Learning process.

What fear and anxiety students may feel in the online courses (see Table 1.2)

Table 1.2 Issues	Frequency % (1=strongly agree, 5=strongly disagree)					Mean	Mode
	1	2	3	4	5		
Q11. The biggest anxiety is not communicating well	3.8	29.4	45.8	18.9	2.1	2.86	3
Q12. The fear is not being effective in using emails	4.6	13.4	32.4	36.1	13.4	3.40	4
Q13. Don't like to be responsible for learning IT	0.0	7.6	49.6	36.1	6.7	3.42	3
Q14. Create more problem than it solves	1.7	12.0	35.0	39.7	11.5	3.47	4
Q15. Had some serious doubts to perform well initially	1.7	17.4	25.5	41.7	13.6	3.48	4
Q16. Not easy use the OLE system	1.3	13.6	30.9	46.6	7.6	3.46	4
Q17. Felt troubled to learn both IT and subject matters	1.7	13.1	42.4	34.7	8.1	3.34	3
Q18. E-communication skills prevent me from sharing	1.7	13.1	42.4	34.7	8.1	3.34	3
Q19. E-learning is suitable for my learning style	11.5	41.3	31.5	13.6	2.1	2.54	2
Q20. Could not overcome the anxiety and fear	0.9	9.8	32.9	46.2	10.3	3.55	4

A question asked if students were anxious about communicating on line in an open discussion forum. Overall, 21% of respondents indicated that they were, 44% of them expressed their disagreement, and 46% were neutral. All respondents were asked to give their view on the statement "My biggest fear in using a computer is not being effective in using emails". Eighteen percent of respondents indicated their agreement, 32% of them were neutral, and 50% of them disagreed. Responding to the statement "Using the OLE for study created more problems for me than it solved", 51% of respondents indicated disagreement and only 14% agreed. Another question asked of all respondents was about the anxiety of using OLE. The statement "when I found out that this course was heavy on technology use I had some serious doubts about my ability to perform well" received a positive response, with 55% of respondents indicating disagreement and 19% saying that they agreed. In response to the statement "I am troubled by the idea of having to learn how to use technology while at the same time learning my subject matter", 43% of respondents disagreed and 15% expressed their agreement. Overall, students felt not too afraid or anxious in online courses. Instead, the statement "The idea of learning on line is suitable to my style of learning" drew agreement from 53% of respondents, while almost all the rest express a neutral opinion (32%) rather than outright disagreement of 16%.

How students evaluate the effectiveness in the tutoring process (see Table 1.3)

Table 1.3 Issues	Frequency % (1=strongly agree, 5=strongly disagree)					Mean	Mode
	1	2	3	4	5		
Q21. Tutors are knowledgeable about e-learning	18.5	55.5	23.1	2.9	0.0	2.11	2
Q22. Tutors give detailed explanations through e-tutorials	12.7	38.8	40.9	7.2	0.4	2.44	3
Q23. The interest in IT for learning has grown	20.1	51.3	23.9	3.4	1.3	2.15	2
Q24. Hands-on tutorials in using IT are appropriate	14.5	54.0	29.8	1.3	0.0	2.17	2
Q25. Tutors email to clarify queries and course requirements	11.1	36.3	44.0	7.3	1.3	2.51	3
Q26. Tutors always reply emails promptly	9.0	27.4	60.3	2.1	1.3	2.59	3
Q27. Tutors are patient with learners	12.0	41.9	44.0	1.3	0.9	2.37	3
Q28. Tutors make use of 'Discussion' for e-tutoring	5.6	28.3	55.8	8.6	1.7	2.73	3
Q29. Tutors are effective at e-tutoring	8.2	39.2	47.8	3.4	1.3	2.50	3
Q30. E-tutoring increases more interactions	8.2	45.9	40.3	3.9	1.7	2.45	2

BEST COPY AVAILABLE

A great majority of respondents (74%) agreed that their tutors were knowledgeable about OLE. Tutors were found helpful in providing detailed explanations in tutorials. During the course(s), 71% of respondents agreed that their interest in use of computers and the Internet technology is growing. All of the respondents were asked if their tutors replied to email promptly. Thirty-six percent of respondents agreed while 60% of them were neutral. The statement "My tutor was effective at e-tutoring". Forty-seven percent of respondents agreed while 49% of them were neutral. Finally, 54% of respondents agreed that "e-tutoring increases interaction between tutors and students when compared with other print-based courses". Only 6% of them expressed their disagreement.

How students evaluate the effectiveness of course co-ordination (see Table 1.4)

See Table 1.4 Issues	Frequency % (1=strongly agree, 5=strongly disagree)					Mean	Mode
	1	2	3	4	5		
Q31. The OLE server could easily be reached	17.8	53.0	23.5	4.8	0.9	2.18	2
Q32. The response time of OLE is acceptable	11.7	61.3	20.9	5.7	0.4	2.22	2
Q33. The supplementary course materials are helpful	18.3	59.1	20.4	2.2	0.0	2.07	2
Q34. Communication and collaboration can be enhanced	10.4	50.9	33.9	3.9	0.9	2.34	2
Q35. E-learning can help extend students' knowledge	11.3	53.0	31.7	3.9	0.0	2.28	2
Q36. It is effective at administrating the course online	17.0	42.8	37.2	1.7	1.3	2.48	3
Q37. It is better than that of other print -based course	16.1	38.6	40.9	3.5	0.9	2.54	3
Q38. TMA could be submitted, assessed and returned online	20.2	49.1	23.7	5.7	1.3	2.19	2
Q39. Prefer to take an online course again	15.0	46.7	31.3	6.2	0.9	2.31	2
Q40. E-learning meets the professional and workplace needs	20.0	53.0	24.3	2.6	0.0	2.10	2

Most of the time, respondents (71%) could reach the course server to access course materials. When connected to the server, the response time was acceptable to them. The supplementary course materials, such as presentation files, tutorial notes, course information, etc were found to be helpful. Regarding the course coordination, 60% of respondents agreed that the course was being effectively administrated and 37% of them were neutral. Sixteen percent of respondents agreed that the course coordination performed much better than if they were in an ordinary setting while 41% of them were neutral. Respondents (69%) believed that assignments could be submitted, assessed and returned online. When a choice is given, they (62%) would prefer o take an online course again. All respondents were asked to give their view on the statement "Overall, I would ate e-Learning as useful to my future, professional, and workplace needs." The response is strongly positive. Seventy-three percent of respondents agreed, 24% neutral, and 3% disagreed.

Conclusion

The challenge of Lifelong Learning and the knowledge-based economy require us constantly upgrading and expanding our skills to meet the future, professional and workplace needs. Technically, e-Learning is feasible for distance learners. Although anxiety and fear in using IT during the e-Learning process were reported initially, technical support, e-tutoring, and e-course administration could reduce these problems substantially during the course. It is well validated that the e-course could improve not only the quality of teaching and learning but also the cost-effectiveness of course administration.

The use of Internet in a PBL course at ITESM.

Ma. Magdalena Maldonado Avalos.
Instituto Tecnológico y de Estudios Superiores de Monterrey
Campus Estado de México
mmaldona@campus.cem.itesm.mx

Abstract: This paper is about how the Internet can improve the process of solving problem in a course design with the didactical technique called PBL (Problem based learning). Firs I presented the differences between the new model and the traditional. Second, what is PBL and the characteristics of good problems. And finally, the 7 steps of the process of solving problems and the use of Internet.

Introduction:

At Instituto Tecnológico y de Estudios Superiores de Monterrey (ITESM), we are working in a new model called "Rediseño" (redesign) , this model was designed in order to achieve the Mission 2005. The principal characteristic of this model is a new different role of the student: he or she has the responsibility of his or her learning.

In the next scheme it is possible to see the difference between the Traditional model and the new model:

	Teacher	*Student*
Traditional model	Transmit knowledge He is the only who evaluates He decides what and how is the process	Teacher's dependence Receptive Individualist
New model (Mission 2005)	Planner and designer Facilitator and guider Share with the students the decisions of the process.	Autonomous Participative Collaborative Engaged with the learning process.

So the students need learn to learn, this implies their role is active. That´s the reason why there were select four didactical techniques:

- ✓ PBL (problem based learning)
- ✓ POL (project oriented learning)
- ✓ CASES (cases method)
- ✓ CL (collaborative learning)

I am working in the Marketing Department. The class I teach is Marketing Services, and I decided to use PBL as the main didactical technique.

Characteristics of PBL

PBL is any learning environment in which the problem drives the learning. That is, before students learn some knowledge they are given a problem. The problem is posed so that the students discover that they need to learn some new knowledge before they can solve the problem.

The big deal is to design a problem that motivates the student, so they can understand why they are learning the new knowledge. Learning in the context of the "need to solve a problem" also tend to store the knowledge in memory patterns that facilitate later recall for solving problems. Problem solving is the process used to solve problem, so the students working in a PBL environment should be skilled in problem solving or critical thinking.

Characteristics of good problems

Some factors that are essential for good problems are:

1. An effective problem must first engage students' interest, and motivate them to probe for deeper understanding of the concepts being introduced. It should relate the subject to the real world, so that students have a stake in solving the problem.
2. Good problems require students to make decisions or judgments based on facts, information, logic and/or rationalization. Students should be required to justify all decisions and reasoning based on the principles being learned. Problems should require students to define what assumptions are needed (and why), what information is relevant, and/or what steps or procedures are required in order to solve them.
3. Cooperation from all members of the student group should be necessary in order to effectively work through a good problem. The length and complexity of the problem or case must be controlled so that students realize that a "divide and conquer" effort will not be an effective problem-solving strategy.
4. The content objectives of the course should be incorporated into the problems, connecting previous knowledge to new concepts, and connecting new knowledge to concepts in other courses and/or disciplines.

Relation between Internet and a PBL Course.

The model "rediseño", also known as The New Model, means that at ITESM we are working not only in the academic topics, we are considering also abilities, attitudes and worths. Also, this implies the use of a technological support that can be: Lotus Notes - Learning Space. (LN-LS), or Blackboard (BB).

In order to teach a class in this model required that all the design and the material that will be used during the period of classes be in the (LN-LS). Before to teach a class in this model a teacher must work in the design of the class. Next table show the database that are used in LN-LS and BB.

Database	LN- LS	BLACKBOARD
Schedule	Here we can find the programming of all kind of activities divided per week. (Our courses have 16 weeks)	
- Start Here		Course Information
- Weeks		Assignments
- Calendar		Course Calendar

Media Center	Here we can find all the material that supports the course: Videos, abstracts, presentations, printed advertising, etc.	Course Documents Course materia ls External links
Course Room - Discussion - Assignments	This is the space designed for make and send the homework (assignments) and the discussions, and also through this database the teacher can graded the tasks.	Discussion Board Virtual classroom Digital Dropbox
Profile - Instructor - Students - Groups	Here we have all the information about the participants of a course (instructors and students). And also here the students can know their grades and the annotations that the teacher made related to their work.	Staff information Use /modify users Groups
Assessment -Questions -Assessments	This space permits to create different types of evaluation like : quiz, exams, survey, self-Asses.	Assesments Pool Manager Online gradebook

Each course is created in a server at each campus. Then each student needs to replicate the course in his or her Laptop through the use of the WEB or the Intranet. So all the activities that a course implies are in the technological support. (LN-LS or BB).

The most important thing in PBL is the relation between the knowledge and the students, Internet is the most easy way of getting knowledge. The student can get information from his laptop, in the moment that he need the information, he can travel through Internet and get it.

In order to solve the problems, the methodology implies 7 steps.

Steps	***Description***	***Use of Internet***
1.Clarifyng terms (In groups)	Have the same information. Identify if there are some terms that need to be investigated.	To search the terms that are not clear.
2. Defining the problem (In groups)	Delimitate the topic	
3. Brain storm (In groups)	Give different alternatives to solve the problem, that need to be investigate.	
4. Classification of ideas (In groups)	Classification of ideas and their relations.	
5. Formulating the learning objectives. (In groups)	Based on the explanations, define what knowledge will be investigate.	
6. Self study (individual)	Make the investigation	Each student make this point, Internet is a good way to find the

		information.
7. Oral or written report by group.	Participate in the discussion in order to make the report.	The students share the information they found, and they can use the information that they found in Internet.

Conclusions

As a conclusion, the process of solving problem without Internet, it could be possible, but it takes a long time to get the information. Fortunately, nowadays we have Internet, so the process of solving problems of PBL, is quickest and more interesting to the students, and let them to have contact with the real world and how the knowledge can be used, some of the characteristics of good problems of PBL.

A Distributed E-Learning Tool Based on Learning Objects

Marco Grossi, Mauro Marinilli and Alessandro Micarelli
Università di Roma Tre, via della Vasca Navale 79
Rome, Italy
contact@marinilli.com

Abstract: We present in this paper an intelligent educational system employing a distributed, agent-based software architecture implemented using intelligent agents, P2P and collaborative CBR techniques. The system answers to user information needs by proposing a tailored sequence of learning objects on the given topics found over the Internet. Such learning objects are packed according to a pedagogical approach and the user characteristics. The system can be seen as an intelligent information searching engine at a higher abstraction level, capable of solving extemporary or continuative information needs by means of user-customized presentations (sequences of one or more Learning Objects, tailored to the current user). Instead of presenting documents passively gathered throughout the Web as current search engines do, it tries to explain the requested information need by means of a sequence of learning objects, found in a collaborative way by querying its fellow agents over the Net.

Introduction

Emerging specifications in E-Learning content representation have the power to foster a whole new host of intelligent services, though such potential is still largely unexploited. Our objective was to design from scratch a new intelligent educational system, that took advantage of adaptive technologies while adopting novel E-Learning specifications, as well as employing a distributed, network-centric software architecture. We used these techniques in an attempt to enhance the quality level of the Internet search process (using annotated learning objects instead of simple documents) while enhancing the quantity of the retrieved material (by using a P2P-based, distributed approach).

We are developing a distributed E-Learning system based on collaborative CBR (Case-Based Reasoning [Aamodt1994]) and User Modeling employing standard specifications for Learning Objects (as prescribed in ADL SCORM and IEEE LOM) and other related standards. The system can be seen as an information searching engine at a higher abstraction level, capable of solving extemporary or continuative information needs by means of user-customized presentations (sequences of one or more Learning Objects, tailored to the current user). Hence, instead of presenting documents passively gathered throughout the Web as current search engines do, it tries to explain the requested information need by means of a sequence of learning objects, found in a collaborative way by querying its fellow agents over the Net. The system is also able to create elementary Learning Objects that encapsulates simpler documents, providing a degree of reliability based on user satisfaction. Also solved information needs (known solutions to cases posed by users) are kept in the local agent library for future use so enlarging the overall available knowledge on the given domain. We used a collaborative CBR approach to manage the information needs. We employed CBR for creating new solutions re-aggregating parts of old ones using P2P networks of domain experts agents. We found this approach well-suited for the inductive nature of our information-rich problem-solving situation. The system is currently used as an extemporary information searching facility, on a restricted domain of interest where a human expert has provided a set of annotated Learning Objects. The system integrates such course material with documents extracted from a well-known Web search engine.

The typical scenario could be the following. A student wants to know more about a given topic, "Java Server Pages". After posting the query to the User Agent, this latter one invokes the Pedagogical Agent that creates a particular Infoneed representation (the current problem representation in our CBR system) relying on the user model, the chosen pedagogical approach and the user input. This data is submitted to a Domain Expert Agent, that coordinates a group of interacting experts (such experts are implemented as peers in a peer-to-peer network) that implements a collaborative CBR process. Each expert peer using its local CBR engine provides a set of candidate solutions (a given sequencing of learning objects plus other pedagogical data) that are newly adapted by the leader domain expert agent. The resulting solution is adapted again by the Pedagogical Agent for appearance and to match the current user needs. The final result is proposed to the user. that can give some feedback that is used to tune both the user model, the pedagogical approach chose and the content. We adopted a distributed algorithm based on the classic CBR nearest neighbor case retrieval technique for case indexing and retrieval. From a CBR point of view the system performs a complete, distributed CBR lifecycle (composed of the four steps Retrieve, Adaptation, Revise and subsequent Retain).

Architecture

The architecture can be described adopting the following functional decomposition:

- the **User Agent**. It acts on behalf of the user, provides the GUI to his/her and interacts with the Pedagogical Agent in order to solve the current information need. It uses a User Model in order to better suite the End User needs. Its proactivity is achieved in two ways. One towards the End User, following the user interface agent approach (as in [Maes1994]). The other is towards the Pedagogical Agents, querying autonomously for new information needs on behalf of the End User.
- the **Pedagogical Agent**. It is responsible of refining the information needs posed by the User Agent, to negotiate possible solutions with Expert Agents and to adapt the found solutions to the current User Agent. The Pedagogical Agent is responsible to bridge the information need as perceived by the user into an annotation suitable for automatic indexing by means of a CBR indexing module. For doing this, it uses other information apart from the user model and the information need he / she devised: a pedagogical strategy, and other context data. In future versions we plan to adopt different pedagogical strategies.
- the **Expert Agent**. It is the knowledge warden, organized as a case library. When queried for some information need it is capable of performing a distributed search among its fellow peers over the Net in order to find the most suitable Learning Objects. It adopts a specialized collaboration CBR algorithm. There are several different types of such an agent. The standard one, that acts as a pro-active CBR library for solving known information needs based on the past experience. Another type is interfaced with a standard authoring tool for allowing human experts to input Learning Objects (though this is a temporary solution, future version will use a specialized User Agent for knowledge input). Other dedicated Expert Agents versions are specialized in wrapping existing rudimentary online data sources (such as traditional search engines, news sources, etc.) on-demand. For a better quality the system elects a leader agent.

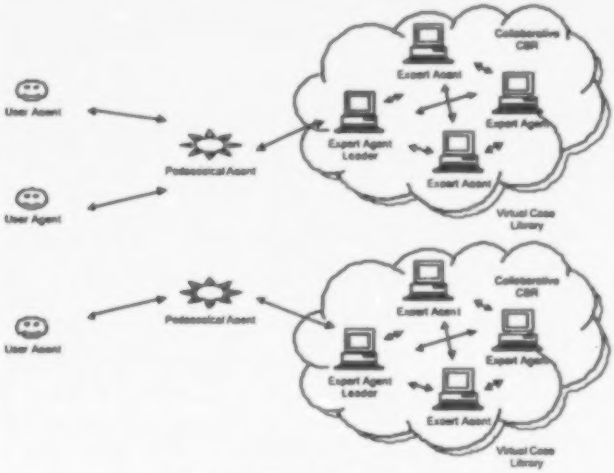

Figure 1. The Architecture

Such an architecture takes advantage of the latest Internet technologies in order to provide a flexible yet robust functional decomposition among the various software modules composing an E-Learning system. Given its top-down, high level approach, this architecture also turns out to be easily understood by non-technical people facilitating their interaction with the system.

Conceptual Model

Our conceptual model is centered around the *Infoneed* concept (an information need posed by the User). This is represented both at an abstract level, and as its concrete implementation (a given sequencing of learning objects provided by the Domain Experts Agents). Figure 2 below describes some of the details of our conceptual model using a UML notation.

Figure 2. The higher-level conceptual model

In our system an Infoneed is represented as a CBR case comprising the following information:

- *User Model*. It is made up of some parts: the *role* (teacher, author, learner, manager, etc.), the *preferences* (type of interactive, format of the resource,...) the *prior knowledge* defined by the *environment* (primary education, secondary education,...,university first cycle,...), the *external context* (type of connection, type of computer, geographical zone,...), *educational needs*, the preferred *learning style* (constructivist, predefined) and other data.
- *Domain information*. It is composed of information regarding the content of the query posed by the user.
- *Learning Objectives*. This comprises information about the target skills, the competencies and the knowledge to be acquired.
- *Pedagogical approach*. It describes a theory of learning and education (empirical, rational and constructivism).the approach is composed by three elements: a teaching situation, a teaching strategy and a presentation method. A lesson consist of four *situations*: an introduction, an analysis part (that contains concepts, definitions, rules, the problem solving strategy,...), a reinforcement and a test. The strategy is implemented by a set of activities (observing, describing, analyzing, experiencing, studying, problem-solving, practicing, exploring, predicting, answer questions,...). The presentation method decides the format of the resources (video, mpeg, html document,...)
- *Learning Object Metadata*, as of the widely accepted IEEE LTSC LOM [IEEE2001].

Conclusions and Future Work

Our system is aimed at filling the gap of intelligent educational presentation, exploiting the best of the two worlds: dedicated, high-quality teaching material (traditionally strongly implementation-dependent) and the wealth of information the Web offers now and it will offer in the near future, when the E-Learning standards will be widely employed. Despite that, given the system capability of encapsulating pre-existing data sources and documents, it can be effectively employed at present time as an E-Learning system specialized in some given domain of interest, with the ability to extract (possibly with a lower quality) information from the Web. Furthermore, E-Learning courses and the related material is represented in a standard and reusable way, to allow exchange with other systems.

As regards future works in the agenda we are evaluating the porting of the system to the EDUTELLA framework [Nejdl2002] as a priority issue. Then we will explore the collaboration mechanisms between different Pedagogical Agents in order to promote a better pedagogical adaptation enhancing the overall learning experience.

Theoretical framework: Towards a Grid for the Pedagogical Analysis of Online Courses

Martine Chomienne
Cégep@distance
Montréal-Canada
mchomienne@cegepadistance.ca

Abstract: After a review of reports on online learning and the evident lack of conclusive studies comparing online learning, traditional distance learning and classroom learning, a research team funded by the PAREA program of the Ministère de l'Éducation du Québec has developed a tool for comparing various online courses. This is based on the theoretical principals of multimedia communication, online collaborative learning and online instructor/student roles. The tool is applied in the learning impact assessment of a virtual program in the natural sciences.

Introduction

E-Learning has become a buzzword in the field of training and education where it is employed loosely to designate a wide variety of teaching situations. Industry Canada in a report from the Advisory Committee for Online Learning published in February 2001 said: "Online learning can be defined as what occurs when education and training (typically credit but also non-credit) are delivered and supported by networks such as the Internet or Intranets. Learners are able to learn any time and any place. In this report, we use the terms "online learning" and "e-learning" interchangeably. In either case, we mean both distance learning and the provision of technology -enhanced learning within a traditional classroom, lecture hall or lab." Therefore, on the one hand, we talk about online courses in which students have more or less infrequent access to web sites associated with classroom teaching and, on the other hand, courses designed entirely to be delivered via the net and followed from home.

Theoretical Framework

The theoretical framework adopted is based on Depover's (et al.) three dimensional model for interactive multimedia (1998), Henri's (and Lundgren-Cayrol) online student collaborative learning model (2001), and Teles' (2000) and Salmon's (2000) online instructor/student roles.

Student/Teaching Material Interactivity. Depover et al. define educational interactive multimedia as the computer-generated integration, distribution, and management of sound, text, and graphic. An interactive multimedia teaching material gains the attention of the learner through the *perceptive channels* (hearing, sight, etc.) and is composed of interactions between the machine and the user. This later must know what the system expects of him in order to navigate properly into the multimedia. Furthermore, interactive multimedia facilitates the *intellectual activity* of the student by proposing *teaching strategies* and by structuring the learning content into different kinds of knowledge representations. It includes all the information needed to build a model *representing the student* and to propose appropriate activities. Each of these intervention levels (perceptive, transaction-driven, cognitive, pedagogical and evaluative) must satisfy clarity, coherency, pertinence, analogy, redundancy and control criteria.

Student/Other Participant Interactivity. The interactivity between the student and the other participants is influenced by collaborative learning and by the role of the instructor. We have regrouped the student collaboration model by Henri and Lundgren-Cayrol (2001), the instructor role by Teles and the stages of student progress in online learning situations by Salmon (2000) into four components describing activities, tools and participant interventions.

Access and motivation allow students to become technically operational and to prepare themselves psychologically for active participation in their learning experience.

Online involvement and socialization consist in building a real sense of belonging to a virtual community and the development of group working methods.

Communication of ideas or information exchange, knowledge building and learner development constitutes the actual learning components.

Coordination includes all the operations that the instructor and the students do for managing the learning experience.

Each component implies interventions made by students and the instructor to be taken into account in some cases at the design phase of instructional material and for others during the delivery phase.

Steps for the Application of the Tool to Online Courses

To assess an online course with regard to teaching, one must examine the student/educational material interaction by determining first the symbolic systems in play. One must then determine the function of each of the system elements as to the five levels of interactivity (perceptive, transaction-driven, cognitive, pedagogical and evaluative) described by Depover et al. (1998). This is the first step and allows us to put together Table 1.

In the second step one must apply the six quality criteria (clarity, coherence, pertinence, analogy, redundancy and control) as proposed by Giardina and Mottet (1996) to each of the elements and for each level of interactivity.

And finally, in the third step, one must determine the elements making up the student/students and student/instructor-expert interactivity. This allows us to produce a series of tables for each component of this dimension. As an example Table 2 illustrates the dimension of Online involvement and socialization.

Conclusions

The tool has been applied to several courses in the virtual program in the natural sciences and has revealed an interesting progression in the use of the internet teaching potential. Courses designed in 2000 were more interactive than those designed in 1998-1999.

Furthermore, the tool is still at the final validation stage with a number of experts in the field. These people are testing it in an iterative process in other courses of the virtual DEC as well as in courses of Cégep@distance.

Supporting Elearning in Engineering Education

Constantino Martins, Isabel Azevedo, Carlos Vaz de Carvalho
Instituto Superior de Engenharia do Porto (ISEP) - Portugal
const@dei.isep.ipp.pt

Lígia Ribeiro
Faculdade de Engenharia da Universidade do Porto (FEUP) - Portugal

Abstract: The purpose of this paper is to present the project "Supporting Elearning in Engineering Education". This project addresses research questions related with the identification of the requirements and evaluation of Web-based learning environments used in an on-campus context, to complement the traditional teaching and learning in engineering institutions of higher education. A set of undergraduate and postgraduate courses of the Porto Polytechnic Scholl of Engineering (ISEP) and the Faculty of Engineering of Porto University (FEUP) will be used as test beds.

Background

The accessibility and easy of use of information and communication technologies (ICT) to develop teaching and learning environments, accessible through a Web interface, is being increasingly explored by academic institutions and companies operating in the education "market" ([Flanagan, 2000] [Collis, 1998]).

The use of these environments as a complement to traditional education in undergraduate and postgraduate courses deserves increased attention. As a result diverse models and patterns have been developed and implemented ([Nachmias, 2000] [Seufert, 2000] [Cardoso, 2001]). Especially because studies show that on-line learning is economically sound and convenientOn-line learning is an important financial market for universities and access to education is enhanced and opportunities are expanded from a political point of view through distance learning opportunities.

Like most higher education institutions, ISEP and FEUP have launched a few e-learning initiatives on an experimental basis, whose results are being evaluated. However these initiatives have not been conducted in a systematic way and have not been integrated with existing information systems, taking profit of the management and communication facilities offered by them. Our view is that Information Systems also constitute an important tool to support the evolution of the pedagogical process (David, 2001). Their interconnection with e-learning systems is expected to have a value added contribution to the continuous education effort.

Objectives

The project will be conducted during the 2001/2002 academic year, focusing on a set of one-semester courses of ISEP and FEUP.

The **first phase** goal was to identify the requirements for a Web Based Environment, which advantageously complements the traditional learning process. For this purpose, a set of tools was designed to provide this information, taking into account the nature of the stakeholders (higher education institutions, teachers, and managers).

We synthesized these studies on these tools as well as case studies in other academic institutions. These results will be published elsewhere (Martins Constantino).

The **second phase** of the project (currently ongoing) will look into the adequacy and advantages of integrating the Web Based Learning Environment with existing Information Systems. The evaluation will take into account the defined requirements and analysis of cost/benefit.

The first step of this phase was the selection, acquisition and installation of a Web Based Learning Environment (WBLE) for each Institution, based on the fulfillment of the requirements identify in the first phase. In order to assess the advantages of the integrating the WBLE with the IS, one of the environments selected (ISEP) will not be integrated with an IS, while the other (FEUP) will be integrated with the existing IS of the Institution, SiFEUP (Ribeiro, 1997).

The next step in this phase has been the analysis of the facilities available on SiFEUP and the advantages of integrating the WBLE with it. This phase is currently under development.
Simultaneously some pilot courses were selected (and a corresponding teaching/learning methodology) in each Institution that will be used to test and evaluate the efficiency of each Institution environment. The assessment, through questionnaire, of student's technological profile was conducted before the beginning of the courses.

As it is difficult to demonstrate that a change in practice or in knowledge over time can be attributable to a single isolated resource (the WBLE+IS, in our case), the Integrative approach therefore looks at how the resource is used in conjunction with all the other resources that are available to its users. It will focus on users' opinions and level of use of the resource, and on how it is embedded into the course as a whole. The opinions of the administrative staff and technicians involved in this study will also be taken into account

Expected Results

The expected results are twofold: identification of the requirements and evaluation of the effectiveness of an integrated e-learning/information system environment in engineering education.

The results of this project may be useful for other engineering institutions of higher education that wish to create, manage access and share Infrastructures of "campus-learning", in an integrated and extensible fashion.

Conclusions

The Results of this project, here summarized, may be useful for other engineering institutions of higher education that wish to create, manage, access and share Infrastructures of "campus-learning", in an integrated and extensible fashion. We also think that the experience of this work represents an alternative view about the role of learning Web-based environments/systems in educational processes.

Learning is facing new challenges in the electronic age, and with no doubt on-line educational communities is one of those challenges where we want to focus ours research work. We think, by exploiting online learning communities, for the complement of traditional education, the academics institutions must consider the learning Web-based environment a strategic instrument of development and research.

Teaching Argumentation in Secondary School Through Computer Based and Face-to-face Debate[1]

Miika Marttunen, Leena Laurinen and Timo Salminen
University of Jyväskylä, Department of Education

miika.marttunen@edu.jyu.fi

Abstract: This article describes a study in which 28 Finnish secondary school students engaged in a 12 week argumentation course. The course consisted of theoretical studies and exercises on argumentation, and argumentative debates in pairs through computer chat and face-to-face. The students' argumentation skills were tested before and after the course. The students also wrote an individual argumentative text before the face-to-face and computer debates and modified their text after the discussion. The test results indicated that the students developed in their argumentation skills during the course. The quality of argumentation in the students' texts improved from the text written before to the text written after the debate. Thus, the debates stimulated students' argumentative thinking and helped them reflect on the topic in question from multiple perspectives.

Introduction

In order to take part in argumentative discussions students are invited not only to construct and transform their own knowledge (Bereiter & Scardamalia, 1989) but rather to co-construct and create new knowledge structures together (Dillenbourg, 1999). For this reason argumentation is a very effective means to learning. Unfortunately, the prerequisites for argumentative co-construction of knowledge are not necessarily met simply by asking students to debate some argumentative topic because, instead of exploring the issue from different perspectives by considering the pros and cons of their arguments, students start very easily to dispute. Although argumentation skills are emphasised as one goal of school education, there is a limited provision in curricula of most countries to teach them . In this paper we present research results based on a teaching experiment aiming at teaching argumentation to secondary school students. The study focuses on the following research questions: 1) Did students' argumentation skills develop during the teaching experiment?2) Are there any differences between students' individually written argumentative texts before and after the argumentative discussions by either face-to-face or by using chat-tools?

Method

Subjects and Measurement of Students' Argumentation Skills

The data of the study were collected in the teaching experiment (12 weeks, 56 hours) carried out in one secondary school in Middle Finland. Before the experiment the argumentation skills of the students were measured by the pre-test. The students of the experimental group (n = 28) participated in the argumentation course while the control group (n = 27) did not study argumentation. The argumentation skills of both the experimental and the control group were measured again after the experiment by the post-test. The pre-test and post-test focused on the students' skills to a) analyse argumentative text by choosing the main claim and the supporting grounds from numbered sentences of the text, b) present their own grounded view (claim and supporting grounds) on a given topic, c) comment on an argumentative writing, and d) to choose valid grounds and correct conclusions from several choices (see Marttunen & Laurinen, in press).

---

[1] The research reported here was carried out within the SCALE project (Internet-based intelligent tool to Support Collaborative Argumentation-based LEarning in secondary schools, March 2001 - February 2004) funded by the European Community under the 'Information Societies Technology' (IST) Programme. Information on the project can be found at: http://www.euroscale.net/

Argumentation Course

The argumentation course was cross-curricular in nature and practically it was a combination of three sub-courses, one in Ethics and two in Mother Tongue. Two of the courses were obligatory (Power of Language and Good and Evil in Man) and the third course (Argumentation) was optional when it comes to the Finnish secondary school curriculum.

The first six week period of the course was based on the combination of the obligatory courses *Power of Language* and *Good and Evil in Man*. Studies during this period followed partly the text books and exercises included in the worksheets of the books. The first period was divided into introductory, theoretical and practical parts. During the practical part the students practised argumentative communication through two topics (Racism and Sexuality) by engaging in informal discussions, drama-sessions, group discussions and group debates.

The second six week period of the experiment was a specialization course of Mother Tongue (Argumentation) during which the students debated in pairs both face-to-face (20 minutes) and by using a synchronous chat tool DREW[2]) (40 minutes). The themes treated were Capital Punishment, Nuclear Power, and Genetically Modified Organism In this paper the focus is on the argumentative chat and face-to-face discussions about *Nuclear power*. The studies in both chat and face-to-face environments proceeded according to a four phase task sequence during which data were collected on students' performance both before and after the discussions in pairs (see SCALE project, 2002a). The *training phase* included one double-lesson (90 minutes) for practicing the use of the DREW software. In the *preparation phase* the students were given newspaper and web articles (5 in total) on nuclear power. They analysed the argumentative structure of the articles in small groups of 3 – 5 students, and presented the results of the analysis to the whole class. After working with the articles the students wrote their first individual text (total of 24 texts were collected). In the *debate phase* the face-to-face group (n = 10) debated on the topic about 15–20 minutes, and the computer group (n = 16) chatted with DREW about 30 – 40 minutes. After the debate the students reflected on the debate by filling in a graph on the debate collaboratively. Finally, in the *consolidation* phase students modified their original individual text as a function of the debate that had taken place. The articles were not available for the students when they wrote their individual texts.

Data Analyses

Analysis of Students' Individual Texts

The analysis examined how wide the space of debate in the students' texts was. The space of debate is wide when the text provides many relevant arguments with respect to the question, and takes into account the multiple points of view that can be held in the debate The analyses of the students' texts are based on a QED (Qualité de l'espace du débat; Engl. Quality of the Space of Debate) analyses method[3]. QED is a numeric measure which is calculated on the basis of the following analysis criteria of the text (for details see SCALE project, 2002b): 1) *Richness:* the text is rich when several arguments are presented; 2) *Elaboration (classification categories: poor, medium, high):* the text is highly elaborative when arguments are provided with sub-arguments, examples, and explanations; 3) *Balance:* the text is balanced when both pro and against arguments are presented; 4) *Coverage:* the text has a wide coverage when the arguments cover many different topics of the question. Coverage is the ratio of the covered topics in a given text with respect to the number of all different topics found when all the texts written by the students are taken into account; 5) *Coherence:* Coherence is the distance between the general opinion of the student (rather *pro*, rather *against* or *shared*) and the general balance of arguments in her/his text .

Pre-test and Post-test Analyses

[3] The QED method was elaborated by M. Quignard (GRIC, Lyon), in collaboration with M. Baker (GRIC, Lyon), J. Andriessen and M. van Amelsvoort (Utrecht University). Details can be found in Deliverable 8 of the SCALE project, at: http://www.euroscale.net/

BEST COPY AVAILABLE

In the analyses of the students' answers to the task of *analysing an argumentative text* the text included one correct sentence which indicated the main claim of the text, and two partly correct sentences. The correct and the partly correct options were awarded by points. The grounds the students had selected were scored on the basis of relevancy to the selected claim. In the analysis of the task of *composing one's own arguments* the analysis of the claims clarified whether the claim a student had composed was understandable and clear in focus. The analysis criteria for the students' grounds were relevancy and sufficiency (see Bacig, Evans, Larmouth & Risdon, 1990; Walton, 1989). The analysis of the *students' comments on a short biased argumentative text* clarified how analytical their comments were. In the analysis of the *judging tasks of grounds and conclusions*, the different possible choices were scored on the basis of rational reasoning.

Results

The students produced higher quality argumentative texts after the debate compared to the text they wrote before the debate (Table 1). The texts after the debate were more covered with respect of the topics, included more and better elaborated arguments, and were more balanced in terms of arguments in favour and against. Consequently, the general QED scores were also higher in the texts written after the debate compared to the texts before. The improvement was equal in face-to-face and computer chat conditions.

Table 1 Differences (paired samples t-test) of the quality of the space of debate and related variables between faco-to-face and computer chat environments

MODE OF STUDY		VARIABLE					
		COV	WSA	WSAP	WSAA	BAL	QED
		% (M)	*ƒ (M)*	*ƒ (M)*	*ƒ (M)*		
Face-to-face (n = 9)	Text before	35.2	6.8	2.3	4.4	30.11	10.6
	Text after	51.2	14	4.1	9.9	39.11	17.9

Computer chat (n = 12)	Text before	38.8	7.5	2.0	5.5	27.7	10.9
	Text after	48.6	12	2.8	9.3	38.5	19.3
	p	*.028*	*.000*	*.108*	*.000*	*.024*	*.017*
Total (n = 21)	Text before	37.2	7.2	2.1	5.0	28.7	10.8
	Text after	50.0	12.9	3.3	9.5	38.8	18.7
	p	*.006*	*.000*	*.008*	*.000*	*.001*	*.001*

COV = Coverage; WSA = Weighted Sum of Arguments; WSAP = Weighted Sum of Arguments Pro; WSAA = Weighted Sum of Arguments Against [The weighting is based on the level of elaboration]; BAL = Balance); QED = Quality of the space of debate.
Note: the range of variables COV, BAL and QED is from 0 – 100.

Table 2 Differences (paired samples t-test) between the students' pretest and posttest results

VARIABLE	EXPERIMENTAL GROUP (N=28)					CONTROL GROUP (N=27)				
	Pre-test	*SD*	*Post-test*	*SD*	*p*	*Pre-test*	*SD*	*Post test*	*SD*	*p*
Identifying claims	.92	.39	.92	.39	ns.	1.11	.42	1.15	.36	ns.
Identifying grounds	.31	.62	.69	.74	*	.70	.78	.56	.70	ns.
Composing a claim	1.08	.84	1.85	.37	**	1.63	.56	1.70	.54	ns.
Composing grounds	1.21	.74	1.83	.39	**	1.62	.57	1.92	.27	*
Analytical approach	.76	.83	.96	.84	ns.	.55	.70	1.04	.71	**
Judging grounds	1.58	.58	1.50	.51	ns.	1.67	.68	1.37	.63	ns.
Judging conclusions	1.44	.71	1.64	.76	ns.	1.19	.75	1.54	.81	ns.

Note: The range of the variables is from 0 to 2.

Table 2 indicates that the students of the experimental group improved in their skills in *identifying grounds* from an argumentative text (pre-test score.31, post-test score .69), *composing a claim* (1.08 vs. 1.85), and *composing grounds* (1.21 vs. 1.83). All the differences were statistically significant. The control group who did not take part in the combined argumentation course did not differ between the pre-test and post-test results in variables *identifying grounds* and *composing a claim* . However, the post-test scores of the control

BEST COPY AVAILABLE

group in the variable *composing grounds* were higher than their pre-test scores. It is, however, worth noticing that the task relating to composing grounds was different in the pretest and post-test: the theme on which the students were asked to compose the grounds was easier in the post-test. The easier theme in the post-test may have affected the students' better scores in the post-test both in the experimental and control groups. For this reason, in the experimental group the difference between scores of variable *composing grounds* in the pretest and posttest was corrected by the effect of the easier posttest task (i.e. control groups .30 improvement in the task), and the difference was tested once again (one sample t-test). The result indicated that the difference remained statistically significant ($t = 2.27$ $df = 25$, $p = .032$; missing values were replaced with the mean).

The students of the control group achieved higher scores in the posttest also in the case of variable *analytical approach* (1.04 vs. .55 in Table 2). The better scores of the control group are most obviously due to a test-wise effect (Borg & Gall, 1989 p. 644) since the task concerning this variable was the same in the pretest and posttest. The improvement in the scores of the experimental group (although not in terms of statistical significance) also supports this conclusion.

Conclusions

The students' texts after the debates included richer topical and more balanced argumentative structure than the texts they wrote before the debate. Thus, students benefited from both face-to-face and computer based debates on the topic. Argumentative discussions during which new approaches and points of view are aroused seem to stimulate students' argumentative thinking and help them reflect on issues in question from several perspectives.

The pre-test and post-test results showed that the students improved in their argumentation skills during the argumentation course. This result suggests that argumentation skills in general can be taught successfully during 12 week teaching interventions. The results are consistent with previous results that have shown that students learn argumentation skills even during shorter (6 weeks) teaching periods (Wesp & Montgomery, 1998). The results are also in harmony with the results of students' improved QED scores in their texts in this study since they support the assumption that during the argumentative debates the students not only improved in their space of debate, but learned argumentation skills as well.

Department of Computer Science
The University of Waikato
Hamilton, New Zealand
M.Masoodian@cs.waikato.ac.nz

Abstract: This paper describes a system for the capture and editing of live lecture presentations for redelivery locally or over the Internet. The system captures both audio from the presenter and the annotations made to the contents of the presentation material. For lecture capture, the system works in conjunction with standard PowerPoint™ presentation software. The audio editing is done using a stand-alone application, while the redelivery is done directly in PowerPoint™, or over the Internet and using a standard web browser. The captured version of the presentation includes the original lecture slides, graphical annotations made by the lecturer during the lecture, the audio recording of the lecture along with controls and indexing methods which allow easy access to different segments of the presentation. Presentations can be replayed in part or in full as required, preserving all of the content of the live lecture.

Introduction

In recent years the use of software such Microsoft PowerPoint™ has become an integral part of lecture preparation and delivery. Lecturers often prepare their material using some kind of presentation software, and then either deliver their lectures directly using the presentation software, or print their notes on transparencies and use overhead projectors for the actual delivery of the lectures. One of the main reasons for the use of printed transparencies, rather than the presentation software, is because it is easier to annotate the lecture material on transparencies during the course of a lecture. Although most presentation software allow annotation of slides during presentation, it is generally more difficult to use a computer mouse to draw or write on a slide than it is to simply use a pen to annotate a transparency. Also, in most presentation software, such as PowerPoint™, the annotations aren't added to the slides, which means that when one moves from one slide to the next then all the annotations on the previous slides are lost.

A further problem in the use of existing presentation software is the lack of support for redelivery of the lecture material. Conventional presentation software at best allows one to convert the lecture notes to Web pages and put them online for students to use after the lecture. However, this is clearly less than satisfactory because the students then only get the notes without the annotations, and more importantly the audio presentation of the lecturer. There is an additional cost here that is not immediately obvious. If it is not possible to annotate or if it is undesirable to put significant content into annotations because it will be lost in redelivery, the lecturer is forced to put significantly more time into preparation, and given a disincentive to vary content at delivery time in response to the questions and needs of the audience. With a good redelivery system, a lecturer could choose the level of advance preparation freely. In particular they could choose to do no advance preparation, except perhaps personal notes.

Although there is software which allows recording of lectures, both annotations and audio content, the majority of these tools place significant overheads on the lecturer to develop their material in a suitable form or using a special application (Jesshope, 2000; Gehne and Jesshope 2000). These overheads often divert the presenter from the real purpose, the delivery of the content, and focus attention on the form. The effort required is typically far in excess of the preparation of the same material for live delivery.

This paper describes the LLC (Lightweight Lecture Capture) software, developed to support the recording of lecture presentations for subsequent review and redelivery, requiring little or no effort in addition to that for the original live presentation. LLC is based on a standard presentation package, PowerPoint™, and requires only that the original presentation be produced in PowerPoint™ format. Capture is based on large interactive display surface technology, while review and redelivery require only a conventional desktop computer.

During this research we have developed a low-cost Large Interactive Display Surface (LIDS) which we utilize for lecture delivery and capture (Apperley et al., 2001). A typical LIDS system is an office whiteboard-sized

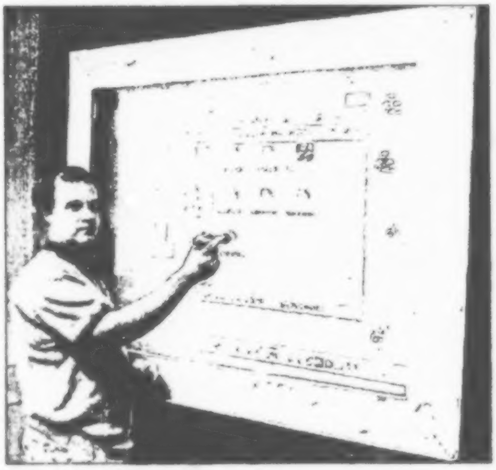

Figure 1: A prototype LIDS system as used for lecture delivery

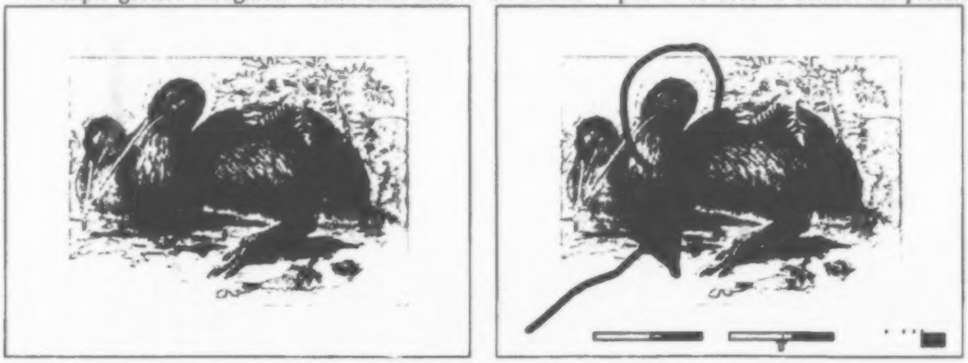
screen functioning as a computer display, with a Mimio™ (Virtual Ink Corporation, 2002) digitization equipment at the front allowing the users to directly interact with the screen using a pen (providing similar functionality to a mouse). A standard data projector and a rear projection screen are used so as to allow the users to work directly in front of the screen without occluding the image. A prototype LIDS system is shown in Figure 1.

Lecture Capture and Redelivery

The Lightweight Lecture Capture (LLC) software acts as an overlay to PowerPoint™, allowing the presenter to make annotations and additions to the individual slides during live presentations using Mimio™ pens. The presenter's voice is also recorded by the LLC software, and together with the annotations is written back into the original lecture notes at each slide transition in standard PowerPoint™ format. Annotations are inserted with timing information and PowerPoint™ animation settings to roughly approximate the time and manner of their drawing.

Figure 2a shows an original slide from a typical PowerPoint™ presentation, while Figure 2b shows the same slide after it has been annotated by the presenter (a circle and an arrow have been added to the image). Figure 2b also includes a set of controls at the bottom of the slide which have been added by the LLC software. These controls (enlarged in Figure 3) include a timeline of the recorded audio track (usually with a few words recognized and shown in the rectangular boxes), arrows giving an indication of the progression of the audio recording when it is being played back, and a set of indicators showing when the slide was annotated.

A simple gesture recogniser within LLC allows the Mimio™ pen to be used to control the presentation.



a

b

Figure 2: a) the original slide b) annotated slide with LLC controls added

BEST COPY AVAILABLE

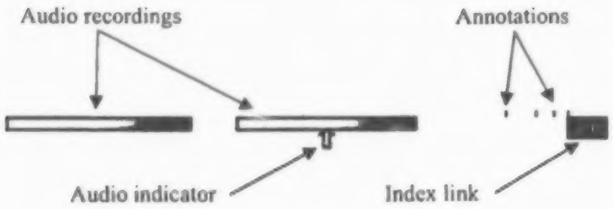


Figure 3: The controls added by LLC

Typical gestures include a right facing arrow to advance a slide, a left facing arrow to retreat through the presentation, and a scribble action to delete an annotation on the current slide. Gestures can also be used to edit aspects of the original PowerPoint™ file during the presentation.

During review or redelivery, which can be carried out on a conventional display screen, the presentation can be indexed at the individual slide level using the standard PowerPoint™ slide sorter view, or the LLC generated slides table of contents. Within an individual slide, animation and audio are synchronized according to elapsed time, although as mentioned earlier, individual graphic components are only crudely animated in themselves. Provision is made to have long silences in the audio minimized to one second, and the annotations resynchronized, again using elapsed time. Further, within a slide, a mouse click will skip forward to the start of the next graphic animation, allowing rapid browsing of both the graphic elements and audio at the annotation level.

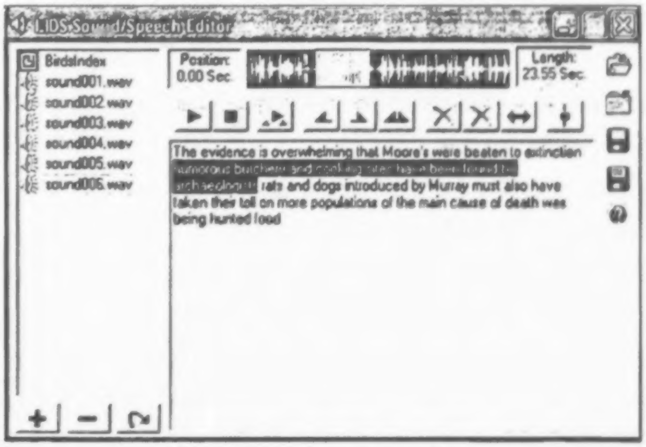
The PowerPoint™ presentation, as updated by LLC can be reviewed by students, using either directly using the standard PowerPoint™ system, or as Web pages with imbedded audio and animations, generated by LLC.

Audio Editing

Since the annotations, additions, and audio contents are written back into the PowerPoint™ lecture notes, it is very easy to further review and edit the slides after the presentation. A stand-alone audio editing tool has also been developed to allow editing of the audio recordings of the lecture presentations (Apperley et al, 2002).

The audio editor reads the contents of a given audio file and uses Microsoft Speech Recognizer to make transcriptions of each audio segment contained in the file. The sound segments are listed in the leftmost pane of the editor window (Figure 4). The example presentation shown in Figure 4 has six separate sound samples. Clicking on a sound sample brings its transcript up in the main text window, and shows a graph of the sound wave in the top window. Selection of text, by click and drag, highlights not only the text, but also the corresponding part of the sound graph. In Figure 4 "h(n)umerous butchery and cooking sites have been found by archaeologists" is highlighted. Selection snaps to whole words because the smallest unit on which the editor can operate is a word, as recognized by the recognition software.

A selected portion of sound can be "dragged and dropped" within the text area. The editor then performs the corresponding operation on the sound file. Spaces between words in the text file have no significance. They are



The evidence is overwhelming that Moore's were beaten to extinction numorous butchery and cooking sites have been found by archaeologists rats and dogs introduced by Murray must also have taken their toll on more populations of the main cause of death was being hunted food

Figure 4: The audio editor

BEST COPY AVAILABLE

added to improve readability. In the sound file long spaces have no mapping in the text file. Short spaces are taken to be part of the immediately following word.

Command buttons are provided to allow playback of either the entire sample, or the sample from a selected point, or the highlighted section. It is often necessary to select and play sections in order to find out what the spoken word actually was meant to be, because the speech recognition is not perfect. The middle group of command buttons adjust the selected area. Sometimes it is inconvenient to drag over a large selection. These buttons allow separate selection of either end of the selected region. The buttons labeled with a cross symbol are provided to delete either the selected segment, or all but the selected segment. The latter operation is the natural one to apply when selecting a small message from a longer text. In using this, it is often convenient to make a rough cut first, taking more than the required length of sound, and to then trim unwanted words from the beginning and end.

As one may notice from the transcribed text in Figure 4, the speech recognition software far less than perfect. However, since the purpose of transcribed text is only to allow locating and editing the sound itself, it is satisfactory enough for the editing purposes. If the user is unsure of a segment of the transcribed text then he/she can easily play it back by selecting it.

Conclusions

This paper has described a prototype system called LLC which has been developed to provide a lightweight capture mechanism for lectures. LLC allows the capture of both graphical annotations as well as the audio content during the original presentation with little or no additional effort on the part of the presenter. Although LLC is normally used with a large interactive display system during the presentations, the captured content can be reviewed and redelivered using the standard PowerPoint™, or a web browser if the content is converted to a suitable form.

A preliminary study of the LLC software in real lecture settings has demonstrated its effectiveness in capturing the annotations and audio contents of presentations. This study has also shown that the students find LLC generated slides very useful for reviewing the contents of presentations after the lectures.

M.Masoodian@cs.waikato.ac.nz

Abstract: Face-to-face meetings between research students and their supervisors are very common. These meetings not only include the verbal interaction between the participants, but also often centre on research documents such as technical papers and reports. Therefore online meeting support systems need to facilitate audio communication as well as shared documents between meeting participants. Although currently there are systems which support audio interaction and sharing of documents, these generally do not provide any linking facilities between the recorded audio and textual contents of the online meetings. This paper discusses the results of a simple pilot study which shows that there is often a close link between the verbal communication and shared document interaction of research meeting participants. A prototype system called COMAP is being developed to allow indexing the recorded audio and textual contents of meetings based on the concepts of *temporal* and *contextual* neighbourhoods.

Introduction

Many university students, particularly at the postgraduate level, often conduct research work in collaboration with supervisors as part of their studies. The students generally meet face-to-face with their supervisors on a regular basis to discuss, plan, and monitor the progress of their research activities. In addition to verbal communication which forms an integral part of face-to-face meetings, research meetings also very often rely on written documents as the basis for discussion. Even when there is no shared document such as a technical report to focus on, the students or their supervisors are likely to take notes for future reference. These shared meeting documents, or personal notes would normally be annotated to include things such as changes, additions, responsibilities, future tasks, and so on which could then be used after the meeting to follow up on things that need to be done.

The audio content of meetings, on the other hand, is usually not recorded, and therefore lost. It is not uncommon for the meeting participants to forget details associated with some part of the meeting which is needed at a later stage. In some cases such details can be retrieved from meetings notes, if there are any, but often it might be necessary to contact the other meeting participants to find out if they remember the details. Clearly in the context of research activities, details or small bits of information can be critical.

An increasing number of students work on research projects with more than one supervisor, who may be located in different institutions or even different countries. In these situations it is not always possible to have face-to-face meetings, and as such, meetings may be conducted over the Internet. However, Internet-based remote meetings suffer from similar problems to those of face-to-face ones. Although there are systems which allow Internet-based audio conferencing, along with access to shared documents across distance, in most cases even if it is possible to record the audio and shared document contents of the meetings, it is not generally possible to link the audio recordings and shared documents.

The objective of this paper is to demonstrate that during research meetings verbal utterances of the participants are closely linked to their interactions with the contents of collaborative documents which form the shared group workspace. It is argued that due to this relationship it is useful to allow meeting participants to randomly access segments of the audio recordings using the indexed links between the audio and the contents of shared document. It is envisaged that such access would be valuable to users searching for information after the meeting. A prototype system is being developed to provide access to audio recording of the meetings using the contents of shared textual meeting documents. The system is based upon the concept of temporal and contextual neighbourhoods (Masoodian & Luz, 2001).

Nature of Research Meetings

The nature of group activities is largely dependent on the type of group task being performed by the participants. The range of research activities undertaken by research students in collaboration with their supervisors is diverse. Any system which aims to support online interaction between students and their supervisors needs to facilitate all these activities, which can be categorized as the following:

- Informal encounters where a shared textual tool acts as a focal point and serves as a medium for exchange of low level details. For instance, when people meet an exchange references, email addresses, etc.
- Formal meetings where a shared textual component acts as a focal point or as a collaboratively built lasting record of the transient speech interaction. For instance, research planning meetings.
- Document evaluation and revision meetings, particularly those supported by shared real-time editors in which text is loaded onto the collaborative tool at the beginning of the meeting, receiving only minor modifications as the meeting progresses. For instance, meetings to discuss a written thesis.
- The variants of collaborative writing described in (Posner & Baecker, 1993) as following a *joint writing strategy* in which people compose the text together, and even small components of the text are decided by group effort. For instance, when a research paper is being written.
- Shared projects, in particular the initial phases of such projects during which people discuss and agree on an interpretation of the problem, define their goals and plan their work, as well as the *integration phase* during which group members integrate their individual inputs. An example of this might be when a students and a supervisor are conducting an experiment.

What is common to all these activities is that they revolve around sharing information in the form of documents. Even when documents are not the focus, in most cases some form of a text artefact is used, such as minutes and action tables. Such documents generally assist people in working on collaborative activities, for instance by reminding them of the responsibilities they may have undertaken during the meeting, or perhaps providing them with information without which carrying out their task may be impossible. It is therefore clear that in many collaborative research scenarios, combinations of speech and text play a central role in the interaction process.

Table 1: Summary of the analysis of the text and speech interaction between meeting participants

Pilot Study

A small pilot study was conducted to investigate the presence of patterns in the speech and text interaction during research type meetings which might be usefully exploited by an online meeting support system. Pairs of academics took part in four physically remote meetings whose goals were to plan and discuss research and teaching. Meeting were supported by an Internet-based audio conferencing tool, and a shared text editor. The duration of these meetings varied from approximately 20 to 90 minutes. All interaction events were recorded and time stamped. A summary of the analysis of the text and speech interaction between meeting participants is shown in Table 1.

Interleave Factor

The data gathered in the pilot study shows a pattern of co-occurrence of speech and text events which may provide valuable clues for information retrieval. In order to assess the impact that these clues might have it is necessary to quantify the extent to which an action conveyed by the speech medium is accompanied by another in text. A metric based on the degree of "interleaving" of text and speech events during meetings, which is call *Interleave Factor* or IF (Luz, 2002) can be used for this purpose.

The meetings evaluated in the pilot study received varied IF scores. Figure 1 shows sample step function plots of audio and text activity for two participants (*A* and *B*) over a 600-second interval. The meeting segment on the left hand side received an IF score of 0.067 while the one on the right hand side received 0.242. It was observed that, in general, the higher the IF of a segment the greater the likelihood that that segment contained relevant information about a particular item, as opposed to low-IF segments where that particular item also occurred. This observation motivates content mapping technique described below.

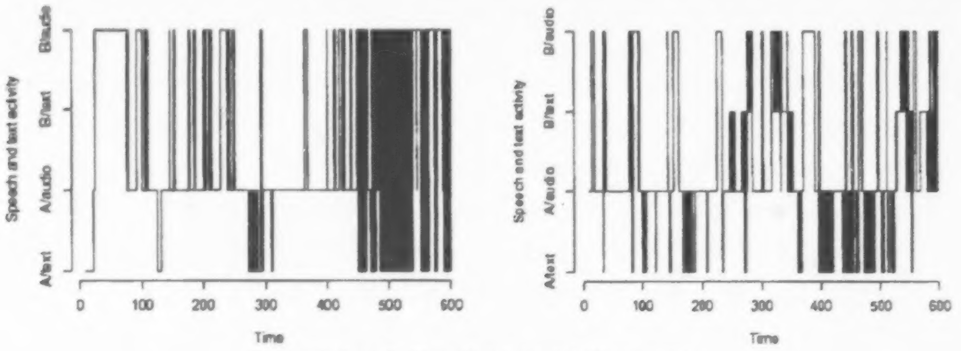

Figure 1: low (left) and high (right) IF segments.

Temporal and Contextual Neighbourhoods

A meeting support tool called COMAP (COntent MAPper) has been designed to allow indexing and retrieval of audio meeting contents using shared document contents. COMAP allows meeting participants to divide the contents of a meeting document into *logical sections*. These sections are then automatically linked by the system to different *segments* of the audio recording using the concept of *neighbourhood*. COMAP defines two types of neighbourhood:

- **temporal neighbourhood:** a segment of audio is in the temporal neighbourhood of a document section if that audio segment was recorded while the section was being *created*, *changed*, or *discussed* by the participants. There can be multiple audio segments in the temporal neighbourhood of a document section, each corresponding to different points in time when that section was *active* (see Figure 1).
- **contextual neighbourhood:** an audio segment is in the contextual neighbourhood of a document section when it shares a number of keywords with that section. There can be multiple audio segments in the temporal neighbourhood of a document section, each corresponding to different points in time when that section was *active* (Figure 2).

COMAP targets two basic scenarios: the system may act as a *listener* while the participants interact through the tools provided by COMAP, or the system may act as an *assistant* for browsing the meeting document along with the audio communication. Currently, COMAP assumes that the shared meeting documents will be textual. Since the text produced as a result of a meeting represents a more structured record of the information exchanged during the meeting, text is the starting point for the content indexing and browsing tools.

COMAP Prototype

A prototype has been built that explores one of the types of information mappings described above, namely, temporal neighbourhoods. The most attractive feature of temporal neighbourhoods from an implementation perspective is the fact that their extraction from a meeting record does not require any speech processing. Time stamps and keyword spotting are all that is needed. Figure 2 illustrates a text and an audio widget linked via temporal mappings. The timeline widget indicates presence of speech by means of horizontal bars stretching along the time axis. The words and phrases highlighted on the text pane are the starting point of the browsing activity. When related clusters of text are selected, the speech event viewer highlights the relevant segments.

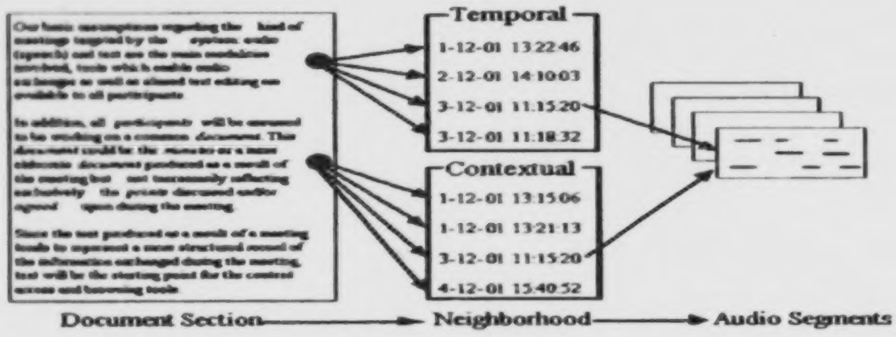

Figure 2: Temporal and contextual neighbourhood mapping

The architecture of the prototype basically consists of a *meeting memory server* and workstations which support a real-time shared editor and multi-party audio conferencing. During a meeting, both text and audio are multicast among the meeting participants using the RTP protocol (Schulzrine et al., 1999), and the COMAP server acts as a passive RTP listener, decoding RTP packets and recording audio and text on disk. After the meeting, these recordings can be accessed via the COMAP client. The shared text editor uses XML technology for tagging text segments and keeping track of document change history. At present, consistency is handled by allowing users to lock a particular node in the XML document tree. In this prototype, users are only allowed to lock paragraph nodes, since we have assumed that paragraphs are the relevant textual unit in temporal neighbourhoods. The audio client uses remote procedure calls to activate playback of audio segments linked to a particular paragraph, and the playback itself is performed via IP multicast. Both the shared text editor and the audio client are written in Java, which guarantees a certain degree of platform independence.

Conclusions

This paper presented an approach to structuring and accessing remote collaborative meeting audio and shared textual documents contents. It builds on notions of contextual and temporal neighbourhoods suggested by the levels of activity interleaving in trial data of student-supervisor meetings.

It is proposed that that our prototype COMAP system will be more useful for meetings which have a high text and audio activity interleave, measured using our notion of Interleave Factor (IF metrics). Future research directions include collecting a larger corpus of speech-and-text meeting data in order to further establish the relationship between IF and effectiveness of information access under varied circumstances, as well as the characteristics of temporal mapping in the presence of richer interaction logs.

On-Demand Learning: Infrastructure Design and Management

Enid McCauley
Director, Product Development and Research
Open Learning Agency

Abstract:
On-Demand Learning: Infrastructure Design and Management, a research infrastructure grant from the Canada Foundation for Innovation and the British Columbia Knowledge Development Fund have provided the Product Development and Research Group at the Open Learning Agency the opportunity to explore new models for K-12 and post-secondary content development, storage, production, and sharing. It has also expanded the role of the Agency in the area of standards development nationally, and provided ways for us to address the issues of cultural change within the organization.

In 2000, the Open Learning Agency received infrastructure funding from the Canada Foundation for Innovation and the BC Knowledge Development Fund to further research and development initiatives into digital learning object design, development, and implementation. This five-year research and development project has had significant impact on the Open Learning Agency both in the way it conducts it's course development activities, and in its ability to play a substantial role in the area of standards development internationally.

The research focus of the CFI/BCKDF initiative is the design and implementation of instructional content, both SGML/XML structured content, and digital video content. It also focuses on learning environments and applications that provide on-demand, self-directed learning. This includes establishing and implementing an enterprise-wide repository for the development and management of "learning objects" (text, image, audio, and video), defining ways to effectively re-purpose and re-package these objects to meet the education and training needs of individuals, and designing web-based learning management systems that provide the learner with the ability to create their own "learning path" from the repository of objects.

The infrastructure being acquired to continue our research into effective strategies for the development and use of "learning objects" at an enterprise-wide level, and even more broadly in terms of sharing information, strategies and resources with partner institutions and programs across Canada, includes:

- Installation of Lightspeed's Astoria digital object repository and iEngine management system
- Development of prototype learning management systems (e.g. Learning Lab) and integration with existing learning management systems (e.g.WebCT)
- Hardware and software for development of digital media objects and structured course content.
- Publishing applications to move from structured information to the web or print.
- Web interface tools for distributed authoring directly into the repository.

Our research and development program addresses the critical design and management challenges facing education and training organizations as they begin to exploit new information technologies. These include:

- How to use structured information models in the design, development and delivery of distributed learning programs
- How to design granular learning objects (text, image, audio, video) that facilitate multiple pedagogical models and enable multiple user requirements in an on-demand fashion
- How to develop multiple output formats to meet particular and individualized client needs from unified development processes
- How to use metadata classification systems to facilitate open learning pedagogy and the transfer of assets between academic and business partners

- How to re-purpose and re-package "learning objects" to meet the education and training needs of individuals and organizations
- How to incorporate an enterprise-wide approach into the design, development, and management of "learning objects".
- How to manage the changing culture of post-secondary content development and delivery from the "cottage industry" to the "learning object" models.

The Open Learning Agency research and development initiatives into structured information are becoming core practice as we begin to change the traditional post-secondary development model. This difficult cultural change requires that a proven prototype in which traditional course designers and faculty can become involved be available for "practice", it requires significant staff training, it requires participation and buy-in from a wide variety of staff, and it requires strong leadership.

The Open Learning Agency research and development plan focused on three major projects to develop and test the model. Initially, we began with structured development in our K-12 program, developing 14 senior secondary courses in SGML for output to the web and to print. This major project, OSCAR, provided a wealth of learning for staff, and became the basis for all our further SGML work.

From this basis, we developed a resource-rich teacher education program using open source technology for self-directed learning (The Learning Lab), and a competency-based business program (the New Management Degree). As more and more post-secondary course development is beginning to follow the structured information process, the key issues which confront us are staff development, implementation of production workflow, output from the repository to high-quality web and print formats, and template design.

This presentation will provide an overview of the CFI/BCKDF project to date, and address the cultural change issues we face as we move towards a learning object economy.

E-Learn 2002 – World Conference on E-Learning in Corporate, Government, Healthcare, & Higher Education
Proposal
(Brief Papers)

Description of Project:

This project addresses the issues of university pre-service and K-12 teachers' perceptions concerning technology and the role of collaboration in utilizing technological applications presented in professional development sessions offered at the university. The dimensions addressed include Higher Education and K-12 in the *Application* domain, Human-Computer Interaction in the *Technology* domain, and Collaborative Learning and Work in the *Strategic Focus* domain. Through funding provided by a PT3 grant (Preparing Tomorrows Teachers to Use Technology Today) at the University of Houston-Clear Lake, university pre-service teachers in their first semester of internship were paired for technology training with their mentor teachers from the public schools. The two groups met at the university for numerous one day workshops which provided training and instruction in areas such as: creating web pages, exploring websites with teacher resources, the use of chat rooms, technology applications in the one computer classroom, numerous technology software packages, and various other computer applications.

After the semester long training, a questionnaire designed by the researcher was administered to 15 pre-service teachers and their public school mentors. The instrument focused on four major areas: 1) technology use 2) attitudes toward technology 3) role of collaboration in learning about and utilizing technology, and 4) perceptions of student engagement potential. Items listed in the questionnaire were determined by examining background literature as well as similar studies. To help validate the instrument, three Instructional Technology professors provided feedback and suggestions on the survey instrument used in the study. After administering the questionnaire, themes and patterns which emerge will be discussed and implications for future research will be noted.

Major Aspects:

The major aspects of the project include a review of the relevant literature and the findings from the questionnaire. The literature review focuses on pre-service and mentor teachers' attitudes toward technology, the ways in which they explore and learn about technology, how teachers incorporate it into their classrooms, and the role of collaboration in becoming literate in the area of technology. The major research questions for this project are:

What types of technology applications do teachers and pre-service teachers utilize?

What types of attitudes do teachers and pre-service teachers have about learning technology-based applications?

What differences, if any, are there among teachers' and pre-service teachers' perceptions about the impact of technology on student learning?

What types of interactions and collaborations (if any) take place as teachers seek to learn about and incorporate technology tools into their classroom communities?

Review of Literature

The review of the literature focuses on three major areas, primarily teachers' perceptions and attitudes dealing with technology, teachers' perceptions of the role of collaboration in learning technology, and teachers' perceptions of the effect of technology on student engagement levels. While there is much written about the evidence that the educational benefits of technology abound (Fletcher, Hawley, and Piele, 1990; Garner & Gillingham, 1996; Kulik & Kulik, 1991), relatively few teachers utilize technology regularly in their teaching (McKinsey, 1996; OTA, 1995). One part of this study seeks to identify the types of applications that teachers and pre-service teachers are familiar with and utilize.

Simply receiving training in technology, though, is no guarantee that it will be infused into the learning environment of the classroom. In a 1998 survey by the U.S. Department of Education, 78 percent of teachers reported that they had participated in professional development about integrating technology into the grade or subject they taught during the last twelve months. In spite of this level of participation, only 20 percent said they felt well prepared to integrate technology into their day to day teaching (National Foundation for the Improvement of Education, 2000).

Perhaps one way to address this issue is to facilitate collaborative efforts within the scope of professional development opportunities. In the process of learning about new technology related applications and making the shift to actual using the information, collaboration can serve as a pivotal force in implementation. Our training at the university sought to do this by allowing the mentors and pre-service teachers to attend the training sessions together. There is much research to show that more sophisticated learning occurs when collaboration takes place. Teaching and learning become interwoven and the learning environment becomes one that is designed for exploration and interaction, and learners are given the opportunity to creatively apply new information (Ferguson & Kopp, 1998). In addition, teachers working together to explore the teaching and learning arena is directly linked to effective schools (Johnson, 1986; Glatthorn and Fox, 1996).

Ideally then, teachers can experience some of the same things we want public school students to experience- engagement with the experience at hand.
Support for this view comes from various sources, starting with the work of Jean Piaget who found that children who are actively engaged assimilate new information more efficiently. The trend in education is moving toward a constructivist view which contends that learning is achieved through relevant, hands-on, socially constructed activities (Ferguson & Kopp, 1998).

The socially constructed nature of learning and the importance of experiential experiences are tapped into to bring about a shift in learners' technological schema. In addition, technology has the added benefit of being a motivational tool. Used appropriately, the use of technology has the potential to affect student engagement. In Means' case studies of 17 classes which incorporated computer usage at nine reform-oriented schools (collected during 1991-1993), it was found that the most common or nearly universal teacher reported effect on students was an increase in motivation (Means and Olson, 1995)

Another promising piece of research shows that exposing teachers to the notion that technology can be an empowering tool to facilitate higher level learning activities can be enough to bring about incremental change. Heath and Burns et al (2000) found that for many teachers knowing how computer technology could be used to enhance learning and being able to plan effective learning activities were more important than having strong personal computer skills. In other words, even teachers who do not feel that they have totally mastered technological applications can begin to think of ways to use technology to advance higher order thinking in their students.

Technology has already had a hand in reshaping business, industry, and the global economy. It has the power to reconfigure the world of education by providing a tool to enhance teaching and learning; but to do this, teachers who currently work in our schools as well as those pre-service teachers who are the future of our schools must be supported and provided with appropriate arenas to explore and implement technology into classroom communities.

The Canadian Design Website:
An Evaluation of Process and Product

Laura April McEwen, Department of Education, Concordia University, Canada, laura@education.concordia.ca

Gretchen Lowerison Department of Education, Concordia University, Canada, gretchen@coreidea.com

Lydia F. Sharman, Department of Design Arts, Concordia Univeristy, Canada, lydia@vax2.concordia.ca

Abstract: The Canada Design Website is a pedagogical resource project located at http://design.concordia.ca/canada_design/. Initially, conceptualized as a pedagogical resource focused on Canadian industrial design, the project has expanded to include the collaborative efforts of undergraduate, graduate and faculty members of the Department of Design Arts at Concordia University. Currently at the end of the second phase of the project, a review of the site to date and an evaluation of the process engaged in by student contributors was initiated. Preliminary findings revealed that learners gained valuable practical experience through this innovative learning initiative but felt that this positive experience might have been enhanced with more clearly defined roles and responsibilities. Several important recommendations from the media/pedagogical expert for improvements to the site included navigation instructions for visitors and enhanced interactivity.

Introduction

A common purpose of course related websites is to serve as an information-delivery medium (Hall, 2002). The World Wide Web has allowed innovative ways to present material. Learners can be presented with text, graphics, animation and multiple ways to navigate through the site. In this multi-media environment, there is an opportunity to engage the learner and enhance the educational experience (Kuh and Vespers, 2001). However, the effectiveness of the media will dependent upon how it is designed in connection with the curriculum (Whitston, 1998).

Hypertext can be used as a cognitive tool. When the learner is presented with material in a hypertext environment, such as the World Wide Web, the locus of control shifts from the designer to the learner. Within this context, learners stand to gain greater control over the learning environment (Hutchings, et al. 1992). Such advantages are dependent upon characteristics of the site design. For example, material might be linked to learning activities that would allow the learner to become proactive, promoting deep-level learning. However, in a more static site, the learner remains passive, knowledge is more declarative and learning is more surface-level.

Background

The site is a scholarly information site presenting Canadian industrial design content. The pilot project was conceptualized in 1996 by Dr. Lydia F. Sharman. As a professor in the Department of Design Arts at Concordia University, she struggled with the lack of pedagogical resources and often drew on personal archive to support her pedagogy. Out of this practical pedagogical need grew the idea for Canada Design Website (CDWebsite). The web offered a particularly appropriate medium as it made it possible to present, in a dynamic form, designers and their products as well as external links to sites of relevance.

During Phase One of the project, content was drawn from Dr. Sharman's archives assembled over a thirty years period. Phase Two of the project involved student researchers developing content from archives and additional primary sources.

An evaluation of the process engaged in by student contributors and the CDWebsite is currently underway. This paper presents the results of the media/ pedagogical expert's review of the site and the preliminary findings from interviews with graduate and undergraduate learners regarding their experiences as content developers. Site development is ongoing and additional data collection and analysis is planned.

The Website Evaluation

Objectives

The purpose of the Website evaluation was to examine the quality of the product to date. The goal of the evaluation was to provide recommendations for improvements to the site.

Methods

Instrument

Evaluation Rubric: The rubric used to evaluate the Canadian design site was developed by the media/pedagogy expert based on the work of Rathswohl, (2002). The following six general areas of focus were identified: (a) General features such as name, URL, author and contributors, (b) Purpose and objectives of the site such as scholarly versus personal, clearly stated purpose and target audience, (c) Navigation and Accuracy such as ease of access, modes of access, internal and external links and accuracy of content, (d) Structure, such as display, quality of graphics and professional design qualities, (e) Pedagogy, such as locus of learner control, interactivity, communication, context, sensory features and information, and (f) Coding features, such as accessibility and browser support of material.

Procedures

Website Evaluation: To meet the objective of ascertaining the pedagogical value of the site, two types of expert reviews were planned: (a) content, and (b) media/ pedagogical. Guided by the evaluation rubric, a media/ pedagogical expert reviewed the presentation and effectiveness aspects of the site. Content reviews with university professors from outside Concordia are planned, as well as several one to one reviews with student volunteers to establish end-users perceptions.

Results

Navigation	• Should be more intuitive, currently visitors must rely on trial and error to discover how to gain access to material. • Links should be uniform throughout the site and easily identifiable as hyperlinks/graphics. • A navigational option other than the browser back key should be incorporated to facilitate returning to the start page.
Pedagogy	• More learner control is recommended. Information is presented fairly linearly, visitors may choose the order of module presentation, but are unable to explore the content of the module prior to selecting it. • Instructions should be made available to visitors unfamiliar with rollover functionality. • Adding an element of interactivity would allow the users of the site to be more dynamically involved and perhaps to exchange information and opinions. This would increase the learning potential of the site.
Coding Structure	• A document type declaration should be added. • The use of frames may cause accessibility problems for those without frame capable browsers, and potentially lead to navigational problems for visitors with disabilities. • ALT tags should be used to describe images on pages for people using non-visual browsers • A title for every page should be included • To facilitate maintenance of the site and reduce the size of HTML files, cascading style sheets could be used to specify font, size and color.

Table 1: Findings and Recommendations

The Evaluation of Process

Objectives

The purpose of the evaluation of process was to explore the process engaged in by student contributors. The goal of the evaluation was to (a) define roles and responsibilities, (b) identify the type and sources of support, (c) determine the personal impact of involvement in project and (d) describe personal learning gains.

Methods

Procedures

To meet the objectives listed above, interviews were conducted with three categories of learners. The details of the process evaluation are presented in Table 2. Learners' responses to interview questions were compiled in tabular form in order of their occurrence and then grouped into categories that emerged from the data. Examples of some direct quotes are included in Table. Ongoing informal interviews with Dr. Sharman also provided information regarding learner support. The instructor of the course *History of Canadian Design* also completed a questionnaire, however these results are not included in this paper.

Results

	Category of Learner		
Information gathered	**Former Design Arts student**	**Graduate student, Design Art**	**Undergraduate** (UG) **Students in *Canadian Design History***
Type of Contribution	Web Designer	Research Assistant/ Content Developer	Content Developers
Define role and responsibilities	Evolved from site developer to include project management aspects and learner support.	Reported initial confusion regarding role and responsibilities. Had anticipated taking on a site development role.	Strictly content development role, • "write short factual summaries on various aspects of the Montreal Metro's design"(UG1) , • "Condense research paper, define segments of intensity"(UG2) Both students hoped the project would allow them the opportunity to engage in web development.
Identified types and sources of support	• Provided guidance to graduate student regarding issues of accessibility related to site design. • Developed template for student contributions. • Provided guidance regarding the focus and organization of content.	Team meetings • held every one and a half months. Dr. Sharman • individual content focused meeting. • Editing via email was fast and informative. Web Designer/Project manager • Discussed web design issues (re: image selection, file format)	Canadian Design History Instructor • provided strong support for the development of research skills. Dr Sharman • provided examples of other contributions and links to completed modules on the site. • Ongoing feedback on drafts via email. Web Designer/ Project manager • offered guidance regarding file formatting, image selection. • provided supported for the content development stage Team meeting—were invited once and found this to be very advantageous.
Determined personal impact of involvement in project	Launched career in Web Design.	"I learnt that design with Dreamweaver is not what I'd want to do for a living"	UG1: access to designer of Montreal Metro for personal interview. UG2: "The opportunity to work with Dr. Sharman, someone with such extensive knowledge and interest in Canadian Design".
Describe personal learning gains	Gained important project management experience.	Improved English language writing and research skills.	• Developed Interview skills (UG1) • Both learners mentioned access to primary source material

Table 2: Preliminary Interview Results

Concluding Remarks

The Canadian Design Website

The Canada Design Project is a very professional looking site. It serves as an information-delivery medium rather than a dynamic site. A search through Google (http://www.google.com) indicates that this is a unique resource for Canadian Design content. In order for the site to become an effective learning tool interactivity needs to be increased.

It is important for the designer to accommodate students' different learning rates and styles as well as diverse background knowledge. In order for the site to be effective, it should attract the attention of the learner but not be so overwhelming that the material is distracting. Hannafin, et al. (1996) points out that students can have trouble navigating in a hypermedia environment when the environment is new. For this reason, it is important to include navigation instructions.

The Evaluation of Process

According to preliminary findings, all categories of student contributors gained substantially from this innovative learning experience. Proponents of constructivist pedagogy support the use of project-based learning initiatives such as these, based on this potential diversity of learning gains (Linn & Burbules, 1993). However, learners' responses indicate a degree of confusion and disappointment regarding respective roles and responsibilities at the outset of the project. Additional data not included in this report would suggest that this confusion was the result of unanticipated challenges related to (a) learner competencies and level of engagement, and (b) limitation in terms of access to technology tools. This inevitably resulted in the subsequent scaling back of student involvement in the web design aspects of the project. Given the obvious enthusiasm for this aspect of the project, it is highly recommended that additional resources be allocated to ensure students more hands on experience with web design in the future.

According to research, the personal attributes of effective leaders have been examined for decades. In fact, during the turn of the 20th century, theorists believed that leaders were born not made (Davis 1998). This premise is no longer accepted in institutions of higher education because of the large numbers of educational leaders graduating from colleges and universities. This research project examined, via technology, the personality strengths and developmental needs of students enrolled in their first semester of course work at Prairie View A and M University.

After almost two decades of school reform efforts in America, there are still millions of children being left behind. Specifically, the Texas Public Schools Statistic (1999) indicates that African American students comprised 18.7 percent of dropouts while Hispanic Americans made up 51.3 percent. According to research, one reason for this failure is due to the quality of leadership as well as the lack of sensitivity to the cultural dynamics within our nation (Wallace Reader's Digest 2000; Astin and Astin 2000).

There is a critical need for educational leaders to develop a keen understanding of the challenges faced by students. Today's students come from a variety of cultures, religions and economic levels; consequently, arriving to school at different ability levels. In addition, environmental conditions may have circumstances that challenge students' time and attention that could or should be devoted to learning. To cope effectively and creatively with these emerging trends, future leaders will need to possess new knowledge and skills as well as displaying a high level of emotional and spiritual wisdom and maturity (Astin and Astin 2000). As the public sector becomes more sophisticated, as well as impatient, critical questions are being asked and stringent limitations will be placed on institutions of higher education. Institutions of higher education play a major role in developing and shaping the quality of leadership in modern American society (Astin and Astin 2000). Thus, it is imperative that institutions of higher education begin to develop a conceptual framework to train and support leaders who will expand the variety and character of their school district's educational programs. After all, it is character, not money that fosters prosperity.

The face of our society is literally being altered due to the tremendous changes in the economic, educational, and demographic forces. The rapid change in the demographics of the United States has made diversity one of the most significant social facets of our society. Due to differential birthrates and immigration patterns, America is experiencing a major ethnic shift with increased numbers of African Americans, Hispanic Americans, and Asian Americans becoming more evident within our schools. In Texas, African Americans and Hispanic Americans youth constitute 53 percent of the school age population and have the highest dropout rate of any other ethnic group within the state. In postsecondary institutions enrollment of the diverse groups are declining. With the continuous increase of a diverse population, it becomes quite apparent that the dynamics of the culturally heterogeneous world have become both complex and problematic. In fact, one of the most compelling needs of our time is to reach for the "forgotten half" of our population who have the capability of leading but are being left behind by the new economy. Specifically, educational leaders do not begin to reflect public school diversity with only 12 percent of the nation's superintendents being female, and only 5 percent being people of color. In addition, leadership positions are expected to increase by 16percent by the year 2008, making it the largest increase of any other major occupation (U.S. Department of Labor, 2000). Thus, creating a greater need for more inclusion of all ethnic groups who have the theoretical and methodological tools to help frame and answer questions that concern all Americans.

Accepting the premise that higher education is the pipeline for developing productive citizens, academia must take the opportunity to lead the way and demonstrate to the rest of the nation how to accept and nurture a diverse community of leaders. Consequently, the question is whether institutions of higher education are up to the challenge of meeting the needs of this diverse population. Therefore, it seems practical as well as necessary for those institutions (HBCUs) that are graduating the largest numbers of diverse students to become an active and viable component in developing leaders, in reforming curriculum standards and providing training for personnel who will lead and educate America's future citizenry. Because education is a continuum (not just Kthrough12), it is imperative that programs/institutions that educate and train preservice and inservice leader become active with educational reform. Since HBCUs facilitate the largest numbers of diverse leaders on the educational continuum, there are needs for leadership centers on HBCU campuses to provide our nation and the world with leaders equipped with new knowledge and strategies for educational reform.

During the sixteenth century, Martin Luther is noted for stating, "...when a man knows his own heart, he knows the heart of other men." Specifically, if educators have a strong grasp of their attributes, learning styles and personality preference they become more in tuned to their students regardless of ethnicity. Consequently, this research was based on the above premise in order for future educational leaders to reach their educational, professional and personal potential, they must be actively involved in developing and implementing instructional models. The primary outcome sought through this research was to promote what Franke, Carpenter, Fennema, Ansell, and Behrend (1998) call "selfsustaining, generative change." Selfsustaining, generative change is when individuals make changes to improve their methods of leadership and instruction to ensure continued growth and problem solving. To ensure that selfsustaining, generative change is on going, a personality assessment was conducted. One's personality is without question the most important driver influencing career choice, relationships, health and sense of well being (Shaughnessy, 1998). To understand the full potential of one's personality, it is critical to first measure and then gain insight into your strengths and developmental needs through examining the results of personality.

In 2001, The American Association of Colleges for Teacher Education (AACTE) cited Prairie View A and M University as fourth in the nation in the production of school administrators. Prairie View, the 2nd oldest institution of higher education in the state of Texas, is committed to providing state of the art training to individuals who will lead and educate America's future citizenry. Data for this research project were gathered during the month of July during the 2nd summer session at Prairie View. One hundred educational leadership students enrolled in their 1st semester of course work were used as research participants for this study. Each student was asked to complete a personality assessment (Keirsey) via technology. Ninety three usable personality assessments were returned. Research participants were also asked to provided additional data in the following areas: Age: 0 through 24, 25 through 35, 36 through 45, 46+; Gender: Female, Male
Career: Elementary, Middle, Secondary, Other; Race: African American, Caucasian, Hispanic. Currently, the data are being analyzed and prepared for presentation. The preliminary findings suggest that over 50 percent of the students assessed are Guardians, which indicates that they have the temperament for leadership!

Distance learning supports: The intentionality of pre-assessment surveys

Patricia McGee
University of Texas at San Antonio

Abstract. One response to high attrition rates in distance learning has been strategies devised to support the learner during their course and, in some instances, before they begin a course. Pre-assessment surveys are the most common pre-course support. This study investigates the content of surveys used in higher education as they relate to research on successful learner attributes. Findings indicate that most surveys are designed, whether intentionally or not, to discourage or eliminate learners who do not posses successful skills, knowledge, or attributes and which may account for reported low dropout rates.

Attrition rates remain higher than in campus-based courses (Phipps & Merisotis, 1999; Kelman, 1997; Naidu, 1994; Garland, 1993; McKinnon, 1993), and tend to be higher for first-time distance learners (Morgan, 2000). Research suggests that although attrition rates are high in distance learning courses, the reasons for these rates are not clear and research has not conclusively identified causes (Sheets, 1992, Thompson, 1997; Parker, 1999). Often demographics (Thompson, 1997) are attributed to attrition, such as learner maturity and motivation, age, gender or instructor experience and expertise (Carr, 2000). Other factors include conflicts with work schedules (Henke & Russom, 2000), poor time management skills, and ill-defined educational goals (Parker, 1995). In those cases where attrition rates are low, explanations are suspect because there is little evidence that success in a distance learning course is nothing more than a matter of learner characteristics. Even for the experienced distance learner there is no guarantee that the context, interactions, or conceptualization of content will resemble previous course experiences. Most distance learning programs attempt to provide services that support the distance learner once they are enrolled in a course to reduce drop-out rates (Oliver, 1999; Morgan, Dingsdag, & Saenger, 1998; Portier & Wagemans, 1995; Wright, 1991).

One commonly used pre-course service is a self-assessment tool that either allows the student to measure his or her preparedness for taking a distance learning course or serves as an anticipatory set[1] by intimating the nature of a distance learning course. Such self-assessment tools are typically in the form of a 10-15 question survey in which the respondent answers 'yes' or 'no' to a series of learner behaviors attributes, or competencies such as those identified by Rowntree (1995): computer skills, literacy/discussion skills, time management skills, and interactive skills. These types of self-assessment instruments assume that the learner will (a) complete the survey, (b) reflect upon and honestly respond to the queries, and (c) take in consideration the analysis when determining to take a course. However, there is no assurance that potential students use the survey to determine whether or not they should take an online course but may serve to eliminate students that do not fit a successful profile.

This study examines US university-delivered distance learning courses, (rather than programs) which are offered as options to brick and mortar campus course offerings. If pre-course surveys are intended as a support to the learner then they should identify skills, knowledge, and abilities necessary for successful completion of the course. An initial review of such surveys (McGee, 2001) suggests that such instruments are written to identify the traits of the *successful* distance learner and whether intentionally or not, serve as a self-selecting tool to eliminate those learners who do not have the desired attributes. The research question is: What content are pre-course surveys derived from?

Method

After searching online course directories, 50 institutions that offered distance learning courses and had Web sites were identified. Each site was examined for online supports to prepare the distance learner; typically these were in the form of a survey or a Frequently-Asked-Questions page. From the 50 sites identified, 38 offered pre-assessment surveys. All 38 were selected as the study sample. Survey items from the 38 pre-assessment surveys were analyzed and categorized holistically. Since many of the items from different surveys were ver batim, it was not difficult to group like items. Categories were determined based on existing ontologies of disciplinary concepts, i.e. motivation, learning style, self-regulation, etc. A literature review identified characteristics of (a) successful distance learners and (b) learner

practices for success in a distance learning course. These attributes where then correlated with topics identified through data analysis.

Findings

A topical analysis of survey items identified three major areas of skills, abilities, and knowledge: environmental preferences, learning preferences, and cognitive skills, see Figure 1. Many surveys were identical suggesting that surveys had been borrowed or copied form similar sources. Due to space limitations, only significant findings are reported here.

Discussion

Findings indicate that pre-assessment surveys focus on either research-based characteristics of the successful learner or extrapolations from the same. For example, maturity is often cited characteristic of a successful online learner. Maturity is often cited as an indicator of persistence, motivation, and responsibility. However, if maturity is often defined in terms of age rather than other indicators which may more accurately define maturity, such as decision-making or problem-solving abilities. Research that explores more deeply into the reported experiences of the learner and their characteristics suggest that learners' reported data might not be reliable (Rubenson & Woodley, 1987). Morgan and Tam (1999) found that when questioned at length about reported reasons for not completing a course or their poor performance, learners often gave very different reasons from what was specified on a questionnaire or survey[4]. Clearly pre-assessment instruments are self-selecting tools to recruit learners with the most likely traits for success. More importantly, few contingencies or supports exist (in most online learning environments) that can aid a potential distance learner in acquiring skills or knowledge necessary to succeed in an electronic learning environment. Without these supports novice distance learners may be at risk of failure (Dille & Mezack, 1991). Additionally, there is no evidence that accommodations for a range of abilities, skill levels, or learning styles are part of distance learning course design. It is a one-size fits all approach assuming that distance learners are a homogenous group. Yet the notion of distance learner as "static" rather than dynamic is increasingly questioned and believed to be invalid (Thompson, 1997; Holmberg, 1995).

---

[2] Self-regulation as it relates to academic settings involves the abilities to plan, organize, and manage learning experiences while accessing appropriate resources, and self-evaluate progress (Bandura, 1997 as cited in King, Harner, Scott, and Brown , 2000). Includes persistence.

[3] Although locus of control is not directly stated in any of the surveys, the attributes of internal locus of control were evident, including: takes responsibility, independent, self-motivated, persistent, and proactive.

[4] Morgan and Tam found that barriers to success and course completion fell into one of four categories: situational, institutional, dispositional or epistemological.

The increasing trend toward transforming face-to-face courses into virtual ones with little or no preparation on the part of the course instructor necessitates informed, calculated, and strategic study and implementation of effective adragological approaches to teaching online as well as providing seamless supports and alternatives for all learners.

The Calibrated Course: Considering the Limits of Standards and Standardization

Online courses at post-secondary institutions are proliferating faster than the statisticians can count. With better than 78% of all higher education institutions offering distance education in some form (nearly 60% offering online learning, National Center for Education Statistics, 1999), it is understandable that issues of quality in distance education should arise. Like the Internet itself, online course offerings have generally come about almost randomly as distance learning programs have produced an online course in whatever subject there was an instructor willing to teach online; hence, developers, administrators, faculty–all seek guidelines in this new instructional medium. Early adopters, entrepreneurs, professional organizations, consortial committees, but rarely faculty and institutions themselves, began issuing an almost steady stream of "best practices" or standards, each claiming to be the definitive guidelines for distance education. In their best use standards have been applied intelligently to complement the criteria worthy institutions already have in place for quality assurance. In less effective use the standards have been recast as a template, enabling a distance learning unit to calibrate its production machinery, cobbling courses for mass production that subscribe to the letter, if not the spirit, of distance education. As Howard and Discenza (2000) point out, "Technology does not replace the human factor in education....technology is not as important ...as some other factors that affect the learning process such as student motivation, learner characteristics, and the professor" (p.153).

While regional accrediting agencies have distance education criteria, those standards issuing from educational organizations hold considerable credence because they are viewed less as evaluative measures and more as development measures. Standards from *DETC, WICHE, SREB, NACADA, ACE, for example, detail pedagogical theory, measurable outcomes, course elements, and other distance learning accoutrements, seeming to suggest definitive molds into which course content and instruction can be poured. A comparison of the lists will reveal very similar approaches to distance education standards. For example, on all lists institutional purpose is a touchstone: "Program is consistent with the institution's role and mission (WICHE)." "Institution has a clearly defined and simply stated mission that describes the general purpose and specific objectives of the institution (DETC)." "The program or course is consistent with the institution's role and mission (SREB)."

Why Do the Rules Sometimes Fail?

There is a common thread running through each list–the classroom model. The assumption appears to be that an online course should feel, look, and sound as much like a classroom course as possible–only "virtual." The underlying premise is that students learn best in a classroom setting; therefore, the more the online course emulates the classroom course, the better. At the same time, detractors of distance learning determine by circular argument that the Internet cannot duplicate the classroom setting and, therefore, cannot provide equivalent instruction. By allowing standards to be rooted in the classroom model, even online course advocates are in effect undermining online instruction.

There are other reasons why a rigid set of rules for online instruction fail to assure quality education. Among them is faculty and course individuality. With the exception of basic courses, seldom does an academic department prescribe how a body of material in the discipline is to be taught. It is assumed that the faculty–the content expert–is the best judge of the sequencing, selection, organization, and presentation of material. This assumption is sometimes optimistic, as few faculty have had pedagogical training. However, most faculty do fair-to-excellent jobs of teaching, simply because teaching involves common sense. The faculty who does not offer students multiple ways of learning, means of assessment, explanations, opportunity for questions, and other aspects of effective teaching usually does so not out of ignorance of method, but of a conscious choice to teach in a particular way. The imposition of standards in these cases legitimately falls as the responsibility of the academic department, not with the distance learning unit. Sensitizing faculty to students' learning needs, not a set of rules, makes for improved teaching online or in the classroom. For the rest, the faculty may well craft the online course to be uniquely his/hers.

Gilliver, Randall, and Pok (1999), like Williamson (1996), insist the act of teaching has not fundamentally changed, but is only assisted by the new educational technologies; "technology provides nothing more than a framework and delivery infrastructure to enable educators to be as imaginative, creative, and flexible as they wish" (p. 18). Some view "best practices" as rules circumscribing a uniform model that may ignore not only faculty individuality, but students' personal learning traits, and even subject matter characteristics. For example, WICHE asks "What provisions for instructor-student and student-student interaction are included in the program/course design and the course syllabus?" The ideal distance learning course or program "provides for appropriate interaction between faculty and students and among students," SREB states. Both of these criteria overlook truly independent study courses, which do not operate with a cohort group, or the fact that group discussions may not be appropriate in courses where learning content does not require peer interaction. As Oblinger, Barone, and Hawkins (2001) point out, "The future of distributed learning—and of higher education—will not be a one-size-fits-all approach" (p. 2).

Why Are There Rules Anyway?

Why rules indeed! Has not the Internet grown like Topsy because it was unfettered and in the hands of the masses? Though the growth of the Internet has seemed entirely spontaneous, the provision of academic credit-bearing courses does require some regulation to assure students of quality. The rules after all are about quality, and to suggest that the some rules are unfounded or may be unnecessarily complicated, tedious, and punitive rather than motivational, is not to suggest that rules themselves are unnecessary. Without rules, anything in HTML could be an online course. Even if it is agreed that a new medium calls for a new orientation outside the classroom model, the growing body of knowledge about learning confirms some generally held beliefs about how learning takes place, and learning is the goal of all courses–online or otherwise.

An online course grounds its quality in appropriate instructional objectives. A course is a quality course in direct proportion to the extent it enables students to meet those objectives. A point here about the relationship between technology and learning: While most distance education programs understand technology and learning are not equivalent terms, there is a still a disjunct between technology and the presentation of content. The assumption that media generate courses implies that games, animations, color, and layers of programming make learning happen better than simple screens with minimal text and straightforward organization. The actual difference in degrees of course quality lies between engaging the learning so that learning may take place and dazzling the learner so that the attention, but not the intellect, is stimulated. It is on this point that standards for production make good sense. Building on a general ambience of simplicity-- "less is more," the quality of production should focus on the basics first, such as ease of navigation, intuitive screens, limited distractions, grammatical accuracy. At this point the technology should become transparent, and the content paramount.

So What Are "Best Practices"?

Best practices are rules-of-thumb generally designed to be emulated; therefore, they are often based on what another institution has done with some degree of success. Best practices can involve the macro-level of institutional or even system planning, or on the micro-level the development of a single course.

At whatever level, best practices should have little to do with trappings and everything to do with the facilitation of actual learning. A quality course, for example, may have or may not have a bulletin board, essay questions, a grade archive, or multiple web links; as Ken White and Bob Weight in *The Online Teaching Guide* say, "teaching is about student learning and deals with establishing conditions for facilitating" (p.vii). Best practices must be thought of in terms of the learner–how does it change him or her? At the least a course presents the material, concepts, skills to be learned. No amount of flash, pedagogical theory, or artificially created community can substitute for a course's prime responsibility to the student–show him/her what is to be learned.

Second, it could be suggested also that a quality course involves metacognitive skills, that is, stimulates the student to think about what he/she is learning, because "learning" is more than cerebral digestion; it is learning to learn. Via the course the student might learn to

a. Connect the content of the course to the larger body of knowledge
b. Demonstrate what she/he has learned
c. Find resources for additional skills, remediation, review, further information
d. Understand the application, particularly the transferability of what he/she is learning

Conclusion:

The online environment is *sui generis*. Its possibilities as a learning environment are limitless. As more advanced technologies become standard on newer computers, succeeding generations of students and faculty will be completely at home in this environment. It is time to take off down new avenues of instruction. It can be assumed that an infinite number of ways of presenting material and of learning material will be possible, that faculty will know distance communication as second nature, as they now know classroom communication techniques, and that students will become completely comfortable with independent learning. Standards and standardization will be only the handmaidens of learning, not ends in themselves.

Abstract: Each new technology brings with it a certain potential for teaching and learning. This potential is based, in part, on the unique characteristics and capabilities of the technology. What can a learner or instructor do with the technology that they cannot do as well with any other? The advent of mobile technologies has sparked a trend, occasionally called m-Learning, or Mobile Learning, which is being touted as the next thing in learning. In this article we present a picture of what mobile technologies and environments may look like in the next few years. We examine the theoretical implications of mobility and ubiquity, the primary characteristics that separate these mobile technologies from other learning technologies. And we discuss the search for a pedagogical model for the creation of collaborative mobile learning environments.

What is Mobile Learning?

Mobile learning is effectively a sub-category of the larger concept of e-Learning. According to Clark Quinn mobile learning is "the intersection of mobile computing and e-learning: accessible resources wherever you are, strong search capabilities, rich interaction, powerful support for effective learning, and performance-based assessment – e-learning independent of location in time and space" (Quinn, 2000). The difference between e-learning and m-learning is an addition of capabilities and limitations, more evolutionary than revolutionary. Briefly defined, mobile learning is the combination of mobile technologies and appropriate pedagogy to allow learners to interact with learning environments, and other learners, at any time from any location. To expand upon this definition, it is first necessary to describe the sorts of technologies and pedagogies used.

Mobile Technologies

Mobile technologies include any system or device that allows a learner to access information or to communicate without the limitations of power cables or network wires. The term could encompass such technologies as radios, portable cassette players, calculators, dictation devices, or alphanumeric pagers. In most cases though, at the current time, the term mobile technologies usually refers to one or more of wirelessly networked laptops, WAP enabled mobile phones, or handheld computers. Future developments of mobile technologies are likely to include convergence, or the combination of several functions in to a single device, eventually leading to a pervasive or ubiquitous computing environment.

Wireless networking, which allows computers and peripherals to share data without being in physical contact, uses electromagnetic airwaves (radio and infrared) to communicate information from one point to another (WLANA, 2001), is becoming more common in educational settings. Handheld Computers are another new technology that is beginning to be seen in educational settings. Handheld computers, sometimes referred to as Personal Digital Assistants (PDAs), are small devices designed to fit in one's hand or pocket. While many companies produce these devices, there are three widely used operating systems (OS) which act as almost generic names; the Palm OS, the PocketPC (formerly WindowsCE) OS, and the EPOC OS. While most handhelds are capable of interfacing with a desktop computer through a synchronization cradle, many of the newer handhelds are being offered with built-in or add-on wireless connectivity. This allows them to connect to the Internet at anytime, greatly enhancing their utility as an educational tool. Mobile phones, and their attendant technologies such as WAP (Wireless Application Protocol, SMS (Short Messaging Service), and mobile Internet connectivity are the other class of mobile technologies that are being used in learning environments. The next generation of messaging services,

BEST COPY AVAILABLE

MMS (Multimedia Messaging Service) will extend the capabilities of these devices by adding media to the messages. This system has yet to be proven in wide scale use.

The Future of Mobile Technology

The current trend towards a single device being capable of handling multiple functions and media types is called convergence. This tend is already visible in the recent release of smartphones such as the Nokia Communicator (www.nokia.com) or the Handspring Treo (www.handspring.com), which combine the functionality of mobile phones, WAP, and SMS with the data processing capability of an Internet connected handheld computer. The idea behind convergence is that phone, computer, audio, video, and Internet can all be combined into one easily portable device. The prototype CyPhone, developed at Finland's University of Oulu (http://www.ee.oulu.fi/projects/CyPhone/), is just one example of such a device. Many futurists predict an era of what is called "ubiquitous computing" where computers are everywhere, in everything, constantly interacting in the larger digital world. Computer will cease to be discrete devices, their capabilities being integrated into most technologies. Ubiquitous computing means a fundamentally different way of interacting with the tools and appliances of our daily lives; and of their interacting with each other (Burbules, 2000). In educational terms this has the potential for tremendous impact. As students become more accustomed to this digital world they will expect, and demand, to see it reflected in the schools.

Unique Characteristics of Mobile Technology

In discussing the merits and capabilities of any technology for use in education it is essential to determine its unique characteristics (Kozma, 1991). The unique characteristics of mobile technologies differ with each type of technology you examine. For instance wireless laptops, PDAs, and mobile phones all have significantly different processor, input, and display capabilities. But they also have certain things in common. The most notable of these, and most important for mobile learning, is their mobility.

This begs the question of what characteristics of mobility may have some effect on learning or teaching. The UniWAP Project (UniWAP, 2002) is looking at the added value of mobility in higher education. They have described three aspects of mobility that impact education: convenience, expediency, and immediacy. Convenience, in their work, deals with the fact that mobile technologies allow a person to engage in educational activities from anywhere they happen to be, even while moving. They point out that while this characteristic seems to have little pedagogical relevance, it does effect how the technology is used. Expediency describes the capability of a learner or teacher to be mobile in some particular place or context that is relevant to the content being studied or taught. Immediacy describes the capability of mobile technologies to allow us to access learning environments or to engage in learning activities at any time, from anyplace, not just when we are sitting at a desk bound computer.

There are other characteristics that can be used to describe mobile learning technologies. Elliot Solloway of the HI-CE project (www.hi-ce.org) often touts the affordability of inexpensive handheld computer, as compared to laptops, or desktop systems currently used in K12 schools. He asks what it means for schools when every student has access to computing technology in the learning environment. While this is a good point it is not always true. At the time of writing, it is possible to buy a handheld computer for under $200, well under the cost of any other computer system with the equivalent versatility. But the more capable devices, those with wireless access and multimedia capabilities can cost more than $600. While still cheaper than even the low-end laptops, this price is equivalent to that of a low-end desktop computer. Perhaps the most intriguing characteristic of mobile technologies it the current trend towards ubiquity. The idea of a person having constant access to a computing device has several theoretical implications.

Mobile Pedagogy

When looking at the use of mobile technologies for learning it is important to determine a pedagogical paradigm that suits the characteristics and capabilities of the technology and the content. The use of modern technologies in education has always allowed the learner to place a certain amount of the cognitive load onto the computer (Scardamalia, Bereiter, Brett, Burtis, Calhoun, & Lea, 1992). Spreadsheets, for example, allow students and scholars to concentrate their limited cognitive resources on drawing conclusions from data rather than spending the cognitive energy performing complex statistical calculations. New wireless and handheld technologies have the potential to increase this effect many times. What will it mean when a learner, whether in a classroom or in the field, has access to the near unlimited information of the Internet, voice and data connections to any number of experts or collaborators, and the data storage and processing power of a modern mainframe; all in the palm of her hand? What will the "effects with" such a technology be? How can we, as educators, design learning environments to take full advantage of these synergistic effects? Distributed Cognition, Situated Learning, and Cognitive Apprenticeship are some of the learning models that researchers are looking at as the basis for a mobile and ubiquitous pedagogy.

Distributed Cognition (Salomon, 1993) looks at the interaction of learners with each other and with the technology itself. Distributed Cognition emphasizes how cognitive efforts are distributed across not only artifacts and internal and external representations, but across individuals and groups as well. In doing so, it dissolves the traditional divisions between the inside/outside boundary of the individual, the technology, and the group. If a learner always has a mobile learning device with him or her, the learner and the device begin to interact, in essence becoming more than the sum of their parts as the learner offloads some of the cognitive effort onto the device, enabling the learner to free up more cognitive resources for learning. If the same device enables the learner to keep in touch with a larger community of learners then the cognition can be distributed over the entire community, as well as their devices, allowing for larger scale social construction of knowledge.

Situated Learning theory (Cognition and Technology Group at Vanderbilt, 1993) is based on the idea that learning that takes place in an authentic context is more likely to transfer than learning that happens in an artificial environment. The Cognitive Apprenticeship model (Järvelä, 1996) is also stresses the idea of situating learning in a realistic context. This means creating learning environments that either mimic the authentic environment where the skills and information learned will be used, or creating a learning environment that actual incorporates the authentic environment. Technology allows for either of these goals to meet more easily. Because mobility allows for learners to go to the authentic environments for their learning, it may be possible to design mobile learning environments that follow the tenets of Situated Learning theory and the Cognitive Apprenticeship model to help support the students' learning. This could lead to the development of location or context dependent learning. That is learning that is greatly enhanced when it happens in a particular location or context. Imagine scientific field work or visits to historical landmarks as the context and think of how a mobile device could allow learners to access pertinent information, remediation, evaluation, or suggested further study as the learner comes in proximity to a location.

Research Findings

Most published articles dealing with the use of mobile technologies incorporate training or K12 and Higher Education been anecdotal rather than research oriented. There have been a few more scholarly examinations of mobile learning, but the field is still very new and in-depth scholarly research takes time to perform and disseminate. Earlier studies looking at the use of laptops, though not specifically looking at laptops with wireless connectivity, showed some benefits and trends which may be reflected, or even increased when those laptops are freed from their stationary connections to the Internet. Some studies noted a shift toward more student-centered classroom environments (Stevenson, 1998; Rockman, 1998), increased student motivation (Gardner 1994, Rockman, 1998), and improved school attendance over students not using laptops (Stevenson, 1998). According to Rockman (1998), a majority of teachers in laptop schools reported an increase in both project-based instruction and cooperative learning. Fisher and Stolarchuk (1998), in a study involving the use of laptops in middle school science classrooms, found that emphasis on the process of inquiry positively impacted student learning and attitudes. Roschelle and Pea (2002) examined the way mobile devices change the way people collaborate and the creation of shared knowledge spaces. Perhaps the largest study to date is the Palm Education Pioneers (PEP) Program (Crawford, Vahey, Lewis, & Toyama, 2002). The report is based on data collected from more than 100 schools around the US who received PEP grants. Teachers using the PDAs gave evaluations of the use of PDAs as instructional tools, with responses over 90% positive. Portability and ease of access were cited as benefits, as were the integration of the handhelds into a variety of instructional activities, the increase in student motivation, and the use of collaborative and inquiry based instructional methods. It must be noted that this research was funded by a handheld manufacturer. Nonetheless, the findings are encouraging for the acceptance of the technology into the traditional classroom.

Conclusions

Distance Education has always been about allowing learners access instructional environments that they could not otherwise access. Mobile Learning is another answer to the same need. But it also provides the opportunity for learners to access those environments at any time or from any place. This extra opportunity for ubiquitous access is the value that mobile learning adds to the educational mix. Mobile learning has the necessary characteristics to become a basic element in the structure of learning and education. The increase in access and the flexibility associated with mobile learning will move students from passive to active roles. They will be able to tailor the content and framework of the qualifications they require, and determine the mode, pace and delivery of study that is best suited to their own personal circumstances. While mobile learning research is still in its infancy, it is obvious that the trend towards ubiquitous computing needs to be matched with a sound theoretical model for educators to make the most of the new technologies.

Abstract: Computers and games are a natural pairing. And these computer games occasionally have real implications in educational technology. In part this is because new technologies are often utilized in computer games long before they make their way into the class room or training lab. In this article we discuss the rise of a new class of computer games, the Massively Multiplayer Online Role Playing Game, and its possible implications for the development of complex social simulations for education and training.

Introduction

New technologies are often utilized in computer games long before they make their way into the class room or training lab. Distributed interactive virtual environments, have long been a goal of educational technologist. Immersive graphical environments where learners from all over the world could interact with each other and with the environment: this goal has been achieved in the online gaming industry and has far reaching implications for education and training. The rise of the Massively Multiplayer Online Role Playing Game (MMORPG), such as Everquest, Ultima Online, and Acheron's Call, has shown that the technology to build this sort of complex virtual world works. The problem is that it is still far too complex for a teacher or an instructional designer to create or run one of these virtual worlds. Recently new games have been released that include a tool set which allows a user to create a virtual space, stock it with artifacts, people it with characters, and run numerous other users through it in real time. Currently the tool set is being used for user created game content. But the same tools can allow a teacher or instructional designer to create a social simulation and adjust it in real time based on the interaction of the learners as they go through the virtual world. These tool sets may turn these games into real instructional tools.

The Origins of Online Games

Before discussing the characteristics and capabilities of current online role-playing games (RPG) it is important to have some idea how they developed and the traditions from which they arose. There are three components that go into the make up of online role-plying games; the traditional role-playing game, the computer game, and the Internet. Today's RPGs developed from more realistic war games, which have been around, and used instructionally, for some time. Napoleon used war games to help train his officers. War games in this case refer to table top games, simulating troop placement and interaction with counters on a map. Chess is a simplified exa mple of a war game. More complex and realistic war games require some sort of rules to determine the results of actions and interactions. There have been many such rule sets over the years. For example, in 1913 H. G. Wells wrote **Little Wars,** a set of rules for war gaming.

But there is a difference between war games and role-playing games. RPGs incorporate the idea of actions and outcomes defined by rules with the setting and narrative quality of traditional literature. Perhaps the most important influence on modern role-playing games has been the J.R.R. Tolkien's **The Lord of the Rings** trilogy, published in 1954. This very popular series introduced a generation to a rich environment of traditional archetypes and mythical narrative structures. After the resurgence of fantasy literature sparked by the popularity of Tolkien's works, there were several attempts to combine the fantasy characters and settings with complex war gaming rules. In 1974 Gary Gygax published the first edition of the **Dungeons and Dragons** rules. This became the first widely popular fantasy RPG. Though over the years since, many other rule systems and genres have achieved popularity, it could be argued that no other game has been as influential in the field as **Dungeons and Dragons (or D&D)**, indeed many use the name D&D to refer to the entire field of role-playing games.

Computers and games are a natural match that has existed since the early days of the technology. In 1962 students at MIT developed what is thought of as the first computer game called **Space War**. In 1969, **Adventure**, a text based fantasy game was introduced. It combined the fantasy setting from the popular literature with the computer's ability to present interactive environments. Once graphic displays became available, games gained graphical features. **Pong**, which first appeared in 1972, is widely thought of as the first "video game". In 1979 Richard Garriot developed **Akalabeth**, one of the first graphical fantasy games. It attempted to be D&D on the computer.

In the years since there have been a plethora of role-playing games on the computer. These games have had certain advantages when compared to table top, or face to face, RPGs. Games on the computer usually include high quality graphics, often immersive 3d graphics that present a world of beauty and grandeur matching those described in books or presented in movies. The story line of these interactive narratives can also be extremely complex with dozen of non-player characters (NPCs), that is characters that are run by the computer rather than the player, with whom the player can interact. And, unlike face to face games, which require that you gather several people into a room together at the same time to play, computer RPGs allow a person to play any time they wish regardless of the availability of other players. On the other hand these games have limitations which are impossible to overcome, based on the fact that the game and all its structure are created long before the player begins play. If a player wants to interact with an NPC, he or she is limited to those interactions predetermined by the game creators. This can lead to a sense of limited choice, as well as social isolation.

The Internet, the world's largest computer communications network, seems like a natural venue for relieving this sense of social isolation, and it has proven so. Since the early days of the Internet, it has played host to various sorts of online gaming. Play by email, where all interaction is non-synchronous and takes place via email, is a modern equivalent to the venerable tradition of play by mail gaming. MUDs, Multi-User Dungeons, are text based game spaces that allow players and game masters or story tellers to interact with each other over intercontinental distances in real time. Virtual Worlds bring graphics to the idea of the MUD. But most Virtual worlds are simply chat spaces with pictures. They lack the rules and narratives of the RPGs. That is what led to the Massively Multiplayer Online Role-playing Game (or MMORPG).

The Massively Multiplayer Online Role-playing Game

The MMORPG combines many of the aspects of its predecessors into an immersive, persistent, gaming environment where dozens, or hundreds, of people from, all over the world can play and interact in real time. These games are characterized by complex storylines and character development, where a story arc can take months of real time to resolve and characters grow and interact for years, instead of the days or weeks most other computer based games last. This long term character persistence leads to complex social interaction and group dynamics. In an MMORPG there may be thousands of players online at any given moment. While the worlds portrayed by these games are large enough that those players are spread out and usually not interacting with all the other player at one time (a recipe for pandemonium when it occurs), they are still interacting with other characters, played by real people, as opposed to dealing only with computer controlled NPCs. This sort of real interaction leads to the growth of complex social structures, some of which are supported by the design and genre of the game, and some of which are not. For instance in some game worlds player characters (PCs) will join together to form ad hoc teams to defeat powerful enemies or pursue difficult goals, while in other games there are formal structures, often called guilds or alliances, where members can benefit from the growth or success of other members.

There is also the potential for negative social interaction as well. Some players choose to use the relative anonymity and freedom of the game worlds to act out anti-social fantasies. This can range form verbal (or in most cases textual) attacks on other players to character assault, murder, and theft. Most MMORPGs are based on some type of heroic adventure genre. And, as in most adventure literature, violence and conflict play important parts of the story lines. In many games it is possible for a player character to attack another player character, even killing them, in game. As players put a lot of time and effort developing a character in these games, character death is seldom permanent. But it usually has some negative consequences. When a PC kills another PC it can cause various levels of consequences to the murdered character, including loss of in game money or goods, as well as taking the player's time and attention. It is even possible for these in game social misdeeds to have real world consequences. Part of the story line common to most MMORPGs is the hunt for treasure. Certain treasured items are very rare and highly desirable in the game world. This has lead to a booming economy in the real world sales of virtual artifacts. For instance a magical sword may be very useful to a character in a game. If one character accumulates more than one of these swords they may choose to sell the surplus. Often this is done on eBay, or some other real world auction service. A virtual magic sword may sell for $100 real world dollars. It is even possible for a player to sell an entire character or account. If a player has spent several months or even years playing a character until that character is very powerful, many choose to then auction that character, sometimes for several hundred real world dollars. This means that if an anti-social character kills a PC who had this desirable magic sword, they might steal it, then sell it for real money on eBay. Some of the social structures in many of these games have evolved to deal with these sorts of undesirable character actions.

There are currently three popular, successful MMORPGs that have been around for several years. The most popular in the US, with membership nearing half a million players, is **Everquest**. It is occasionally facetiously referred to as EverCrack, as it is said to be almost addictive in its draw for its players. It is a traditional fantasy RPG environment based loosely on the D&D game. The second most popular in the US is **Ultima Online**, based on one of the most popular computer based fantasy RPG series. It differs from most of the others as it uses a 2d interface instead of the more common 3d. It is also the oldest of the popular MMORPGs. The third of the "Big Three" is **Asheron's Call**, distributed by Microsoft. It is also a fantasy game, though the environment is original rather than based on some other property. There are several new games that have reached some popularity in the last two years, many which move away from the fantasy genre, and there are dozens of new games under development, including updated versions of the big three.

The Future of MMORPGs

Two trends in new technologies are most likely to affect the shape of MMORPGs in the next several years; the increase in graphics capabilities and the increase in network bandwidth. Combined with the like advent of head mounted displays and kinesthetic feedback systems, immersive virtual reality will take on a new meaning. As the verisimilitude of these virtual worlds increase, so will the involvement of the players. Even as each game becomes more realistic, the development of social structures and game design combine to create more complex interpersonal interactions. What are sometimes called "next generation" games often include mechanisms to discourage or prevent anti-social behaviors. The popularity of, and revenues from, theses sorts of games often lead people to call MMORPGs the entertainment form for the next century. Whether this is more than mere hype, only time will tell.

It is also possible; likely even, that the basic technology that is the backbone for the MMORPGs, the persistent, shared virtual world based on large scale network systems, will spawn other, non-game related applications. In industry it is easy to imagine virtual meeting spaces where groups from around the world meet and interact with high fidelity avatars. It has also bee suggested that this sort of interface could be combined with tele-control systems to have simulated factories building real products or with tele-presence systems to enable real long distance medical procedures. It has even been proposed that this sort of technology be used for virtual conferences where hundreds of people meet, interact, watch or make presentations, complete with slides and video. Tele-government is another potential use of this technology,. Where legislatures and other government bodies meet and vote in a virtual space, which is in turn open to any voter who wishes to attend.

Creating Educational Simulations

One of the most interesting of the new games, and possibly the most important from an educational point of view, is **Neverwinter Nights** (NWN) from Bioware. This is a multiplayer online role-playing game setting in a traditional fantasy setting. It is based on the Dungeon and Dragons rules (3rd Edition) and allows up to 60 players to interact in the environment in real time. The thing that makes NWN so different, and so interesting, is the inclusion of the **Aurora Toolset**. This toolset allows a user to create their own online 3d immersive environment, people it with NPCs, and most importantly, manage the environment in real time as the players run their characters through it. This means a game master (GM) can design a city, dungeon, or landscape, populate it with people and monsters, giving each a series of preset interactions and responses to the characters and their actions, but if those presets prove ineffective, the GM can, in real time, take over the NPC and cause it to reply or act in the manner most appropriate to the player's actions. This sort of control turns the game into a potential tool for powerful immersive, distributed social simulations.

There are four basic types of simulations: physical simulations, which simulate physical objects, i.e. a frog or a machine; procedural simulations, which simulate a particular activity such as flying an airplane or performing heart surgery; situational simulations, in which the learner is a participant in the larger situation, and can interact with and change the environment; and process simulations, in which the learner sets variables then watches the results of a process. The Aurora Toolset seems best suited for developing situational simulations. If an instructor or designer can shape a virtual environment with complex social interaction, then educators can create social and historical simulations, virtual field trips, even virtual classrooms where the learners can interact with each other as well as with the instructors and preprogrammed characters. One example might be a discrimination awareness simulation where the learners take the role of a discriminated minority with in a society. The reactions of the non-player characters, as well as those controlled by the instructors would should both subtle and overt examples of differential treatment for the learners' characters, all with in the context of a larger society. Or it could be possible to reenact the original Constitutional Convention, with learners each taking the role of a delegate from a particular state, trying to represent the views of that state on the important issues being discussed.

Currently the Aurora toolset is both complex to use and limited in its capabilities. The most noticeable of its limitations is the inability of the content creator to break away form the medieval/fantasy graphics inherent in the game. It is likely that a tool, provide either by Bioware, or by a third party developer, will overcome that limitation in the near future, but for the moment any environment or character created will have a definite fantasy flavor to it. One of the questions being addressed in this research is the importance of verisimilitude in these sorts of simulations. How distracting, or detrimental, is it to learners to have the simulated Abraham Lincoln and Jefferson Davis; look like knights in armor or elves, when seated at a simulated peace conference table. At the time of writing, the author and his colleagues are using the Aurora Toolset to develop educational social simulation environments. Later publications will explore the use of the toolset and the effectiveness of the simulation environments.

The Psychological Dimensions of Communities of Practice and their Relation to Online Learning

Dr Donald W. McMurray
School of Social and Workplace Development
Southern Cross University
dmcmurra@scu.edu.au

Abstract: In 1998, Southern Cross University adopted an action research methodology to design and deliver online units. Each action research cycle involves learning and reflection wherein necessary changes are instituted and the outcomes evaluated to assess the efficacy of online learning compared to conventional distance education learning (Hayden, Saenger & Parry, 1999). Feedback was mixed especially with respect to collaborative learning (McMurray & Dunlop 2000).

In a subsequent iteration of the action research cycle a community of practice concept was promoted where students were encouraged to organise themselves into a community of learners with the goal of supporting each other in their learning (Wilson & Ryder 2001).

In the most recent cycle, a conscious effort was made to simulate the culture and climate of real-world organisations (? ? ? ? ? ? ? ? ? ? ? ? ?? ? ?). It was found that the sense of community for online students was in many ways richer than that experienced by face-to-face students.

INTRODUCTION

The notion that the Eclassroom adds increased flexibility to the delivery of distance education is well established in higher education institutions today. Distance is vanishing, time is collapsing and relationships are becoming central to success (Olson 2001). There is also some evidence that the opportunity to interact and collaborate leads to richer learning experiences (Lander 2001; McMurray & Dunlop 2000). It is argued that the effectiveness of online learning activities rests on the manner in which they encourage interactivity and collaboration in establishing a community of learners. This paper examines evidence for the existence of a community of practice concept in an online setting as compared with a face-to-face class studying the same unit.

THE INITIAL ACTION LEARNING CYCLES

Staff within the School of Social and Workplace Development adopted an action research methodology to design and deliver online units within the Bachelor of Social Science. Each action research cycle involves learning and reflection wherein necessary changes are instituted and the outcomes evaluated. The process resembles a hermeneutic spiral (Gummesson 1991) where each turn of the spiral builds upon the understanding flowing out of the previous turn

Since first semester 1999 when five units were offered completely online, there has been an increase in demand by traditional distance education students wishing to utilise this communication technology. Presently 176 units are being delivered online all of which contain discussion forums and group collaborative work areas. In preparing units for online delivery, there has been a deliberate repositioning of the instructor away from the role of knowledge transmitter to that of facilitator, coach and resource guide. Emphasis is given to engaging the collaboration of the students in creating their own knowledge.

At the end of each semester units were evaluated to assess the efficacy of online learning compared to conventional distance education learning (Hayden, Saenger and Parry 1999) using a questionnaire adapted by Dunlop (1999) from Creed (1996). Initial feedback showed that while distance learning students value the interaction with and access to the lecturer, they found collaboration with each other to be problematic, especially where it led to a shared grade.

It was decided to pay more attention to each learner's basic communication needs when operating in a group. Computer supported communication is devoid of important social cues that are important for message validation and, therefore, the building up of trust (Collins & Berge 1996). Moreover, according to Dunlop and Scott (2001), online groups need sufficient time to become acquainted with each other and develop cohesion (King 1999) as well as the necessary social protocols. Only then can successful collaboration take place which, in turn, can lead to the facilitation of shared meaning (Allen & Griffith 1997).

THE PREVIOUS ACTION LEARNING CYCLE

The reflective phase of the initial action learning cycles led to a decision to create a community of practice for online learners since this has been found to be lacking amongst distance education learners (De Vries & Wheeler 1996; Martin

1999). Communities of practice describe informal settings in which people learn by doing. It has its epistemological roots in constructivism which assumes meaning is jointly constructed and arises out of ongoing activities of a community of learners. Here knowledge as well as action is fundamentally social in origin (Henning 1998). Stamps (1997) claims that communities of practice are not actually created but emerge as a function of people becoming united as they work collaboratively towards a common goal.

Accordingly, with the online launch of an undergraduate unit entitled *Organisational Communication*, it was once again decided to focus on a requirement for the students to interact and collaborate. In previous units of study the setting up learner centred groups had been undertaken by the instructor. In this iteration, however, the process of organising themselves into groups was left entirely to the students, including the naming of their virtual organisations. This was an unhurried process that occupied the first two to three weeks of the semester and produced a number of communicative activities, ranging from one-to-one dialogues using email and the telephone to the use of the discussion area inside the course delivery shell by the whole group. Very little instructor-to-learner communication occurred at this stage and this proved to be beneficial for the groups in forging a sense of community amongst themselves.

Once the online groups were established the asynchronous chat room quickly became the vehicle for conducting and archiving discussions. Many exchanges occurred between the two organisations as members explored boundaries and developed a sense of cohesion in and around their new 'organisation'. Initially these discussions were almost exclusively social and yet the creation of this social community served as an important bridge to the formation of the academic community that was to follow.

The evaluation of *Organisational Communication* at the conclusion of semester 2, 2000 confirmed the growing appeal that online learning holds for distance education students. The frequency of visits to the student discussion areas in this unit was almost three times as great as that recorded in two earlier surveys (McMurray & Dunlop 2000). It is contended that this increased interactivity was a product of the community building that took place at the outset of the unit. What began essentially as social interaction transformed into exchanges of a more academic nature. The students could see the merit in interacting with each other in this way. Eighty-six per cent of students rated the real-time chat sessions with other students as having "great value" or "very great value" (Newton & Ledgerwood 2000). In its virtual chat room *CourseInfo* records threads of conversation as online discourse in a way that allows every thought to be captured for future examination, reflection and extension by their peers (Owston 1997). The result is richer, more thoughtful discussions arising out of shared understandings which in turn contribute to a different kind of knowledge building from that which students are able to accomplish on their own.

Reflecting on this action learning cycle it was realised that if meaningful and useful collaboration is to become an integral part of computer assisted education, it is essential that the students are motivated to participate (Prendergast 1996). Further, it appears that for collaboration to be truly successful, the learning environment should be structured by the participants themselves. This includes reaching agreement about shared goals as well as the purpose of the collaborative enterprise.

THE CURRENT ACTION LEARNING CYCLE

The reflections flowing out of the second action learning cycle led to a number of important determinations. First, interactivity which occurs online is qualitatively different from that which takes place in a face-to-face environment. For example, a sense of immediacy is missing, along with an absence of non-verbal cues. For this reason it was decided to encourage the current cohort to make greater use of the virtual chat room. It was hoped that this real-time contact would promote a shared understanding of concepts and allow them to experience diverse and multiple kinds of feedback ahead of that received from the unit instructor. It was also hoped that this kind of interactivity would serve the dual purpose of fulfilling both academic and social needs of a geographically disparate group of adult learners.

The group of students presently studying *Organisational Communication* are all female and include two from the USA. They refer to their organisation as *CyberF.com*. From the outset the instructor once again maintained a relatively low profile while the group set about the business of developing their community of practice. While the instructions were clearly stated in the unit outline, control of the decision making process concerning how unit objectives were to be achieved was placed in the hands of students. Interestingly this type of instructor style was interpreted by one of the students as being somewhat laissez faire.

Towards the end of the unit members of *CyberF.com* were surveyed to ascertain what happens when students congregate to provide mutual support for their learning. The instrument used was designed to reflect perceptions of organisational climate. Moran and Volkwein (1992) see

> ? [as]? ?
> ?
> ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ?views? ?
> ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? ? -
> ?
> ?
> ?

???
??????????????????
??þ.??

At the same time students studying via conventional distance education techniques were also surveyed as to their perceptions about the climate as determined by their learning mode. Differences were found between the two groups with respect to 'cohesion', 'support' and 'trust'. For example, only 21% of distance education students reported feelings of cohesion with the school or their fellow students as compared with 90% of *CyberF.com* students. Similarly, almost twice as many online students felt supported in the studies as compared to external studies students.

Overall, the results provide evidence for the existence of a healthy climate amongst the online group that was not found in the conventional distance education mode. It is suggested that these factors are important requisites to the formation of a community of learners and are themselves the products of sustained interaction and collaboration.

BUILDING LEARNING COMMUNITIES ON THE WEB

There are a number of techniques that can be identified for those wanting to develop effective online courses. First, online learning needs to be viewed as a process not a sequence of structured activities. Action learning offers an appropriate lens through which to view these processes as they unfold.

Second, there should be a deliberate attempt to provide an environment that is intimate, inviting and authentic if quality learning is to occur. Ideally, this can occur within a community of practice. Hill (2001) outlines a number of strategies for establishing online communities of practice. These include:

- appealing to their sense of adventure from the outset by providing a vision that causes an air of excitement;
- providing communicative mechanisms that facilitate interaction;
- ensuring a safe and protected environment free of outside criticism and interference;
- assuring them of a constant connection with the instructor as needs dictate;
- enabling them to interact and communicate in a number of different ways; and
- working hard to avoid or remedy technological problems that may potentially thwart their community building.

Third, encourage a diversity of participants since geography does not matter in an online community. Nevertheless, adequate attention needs to be paid to cultural demographics. Finally, as instructor, it is important to provide the human touch by visiting the chat rooms, staging teleconferences, recording audio messages and sending e-mails. The prime objective here is to encourage students to reflect on their own learning and to analyses these metacognitive activities for future reference.

CONCLUSION

This paper has traced the emergence of a sustained positive shift in attitude towards collaborative online learning for distance education students over a number of action learning cycles. It is concluded that the establishment of a virtual community of practice involving common goals and a desire to learn from each other are key drivers behind the shift. Technology, in and of itself, does not foster collaboration. As Adams and Freeman (2000) found, the establishment of a community of practice serves the purpose of supplying the necessary human infrastructure for the creation of knowledge with the Web providing the technological tool. Student feedback suggests that collaborative online learning yields richer learning than simply requiring individuals to interact with materials that have been web-mounted (Hiltz & Benbunan-Fich 1997).

WEBQUESTS: INSTRUCTIONAL and DESIGN TECHNIQUES

Donna J. McNierney
Beeghly College of Education
Youngstown State University
United States
mcnier@zoominternet.net

Abstract: Using multimedia and computer generated web-based instructional activities; such as the WebQuests is a non-traditional instructional approach for teaching subject area content. This instructional method is designed to meet the learning needs of the student related to visual literacy, problem solving, discovery, and critical reflectivity. Transforming traditional instructional methods using critical pedagogy, promotes the teacher to examine current practice and ways to integrate technology with classroom instruction.

Introduction

This paper has two primary purposes. The first purpose is to review current research related to visual learning and learning theory and to discuss the resulting critical pedagogical implications within teacher education methodology and technology courses. The second is to describe the design of WebQuests as a learning activity so that teacher education students will learn the importance of integrating technology with instructional use in their classrooms as a web-based instructional tool. The learning experience for the students of designing WebQuests helps to challenge the teacher to engage in critical reflectivity of lesson planning and to promote the learner's ability in visual learning, problem solving, and discovery. Inherent in a review of the research is an understanding of the importance of the critical reflectivity process itself. Critical pedagogy theorists argue that teacher education programs must include methods in the curriculum which engage education students in a critical reflective process - a process which results in their discovery and examination of traditional teaching and current practices. Engaging students in this process, using theoretical frameworks from researchers such as Dewey, Jung and Wink, ultimately assists in setting the parameters for designing successful instructional and methodologies which include the integration of technology. As a teacher educator at the university level, my education students in the technology courses need to learn that "critical pedagogy forces educators to look again at the fundamental issue of power and its relationship to the greater societal forces that affect schools" (Wink, 1997). Students need to know how current teaching practice that is enhanced with appropriate and challenging web-based activities, such as WebQuests, changes the teachers role but also gives power back to the students by challenging them using a constructivist approach by using problem solving and inquiry based learning.

Dondis stated that the traditional educational system places too much emphasis on the "verbal mode to the exclusion of the rest of the human senses and with little sensitivity to the visual character of the child's learning experience" (Dondis, 1973). Teaching and learning with visual images is usually of secondary importance in a curriculum. Many educators believe that when students are engaged in a visual learning activity, the learning is often passive, not personal or interactive. The dominant teaching style in traditional classrooms then remains teaching by telling.

How do we provide both the ideological and physical conditions important and necessary to educate all future citizens? How do we challenge all students in the dynamics of critical literacy, constituting a basis for a well-informed citizenry in a democratic society? (Giroux, 1988).

For example, if lecturing remains a popular method in our traditional classrooms, how do we know if it is the most egalitarian? How do we know if most of our students learn by listening through the auditory senses? How do we know that they can apply the principles and concepts of their subject matter merely by hearing? The answer, apparent to most informed educators, is that we do know and the answer is that most students do not and cannot learn merely by listening. How much of the students' learning is through the visual?

Jung's research, however, on psychological type helps to illustrate the importance of visual learning by identifying how students prefer to perceive and interact with their world. Jung's definition of the psychology and structure of consciousness yields "four basic functions which are constitutionally present in every individual: thinking, intuition, feeling and sensation" (Jung, 1992). These functions are also referred to as the functions of consciousness or typology.

John Dewey, another prominent educational theorist, contributed interest and effort to the learning process. Dewey (1985) stated that the learning experience of the student is enhanced when interest is "secured in a given set of factors or ideas; we can be perfectly sure that the student will direct his/her energies toward mastering them" (p.159). According to Dewey, the level of interest in a given topic and the amount of effort it takes to complete that task, "necessitates that genuine interest is the accompaniment of the identification through action, of the self with some object or idea, because of the necessity of that object or idea for the maintenance of a self-initiated activity" (Dewey, 1985, p.159).

Interest is first active; second, objective; and third, personal. To be interested in performing a task, students must have a direct concern in it and recognize that because of this required personal commitment the outcome is important to them. Students must identify the task/idea as their own and thereby achieve both a sense of pride as well as a positive self-concept when their goals are met. Due to the personal interest attached to the attainment of the goal, students are willing to put forth the effort. The cliché, time flies when you are having fun, is appropriate in describing the students' interest level.

Nowhere are Dewey's ideas more pertinent in today's educational process than in how they relate to visual learning. How many times have students failed to correctly answer a geometry question but won a friendly game of pool? To play the game first hand requires both visual and critical thinking of the laws of physics and geometry and an interest. Students who cannot successfully memorize the mathematical formula for a passing grade can successfully envision a bank shot into the corner pocket. They understand the concept of angles and speed and apply them first hand -- because they are interested and because they are visual. In essence, they are successful in decoding the images.

For a lifetime of learning and literacy that extends far beyond the walled boundaries of a school, the learned ability to accurately recognize, identify and interpret visual messages, actions, objects, and symbols encountered in the world is an important critical element in encouraging the processes of reflectivity and critical literacy. Visual images are a language, visual literacy is the ability to understand and produce visual messages (Heinich, 1996). Recent research and study in the field has focused on the importance of the development of teaching and learning strategies to increase students' abilities to evaluate, create and think critically about the images presented. Findings from the visual literacy field of research are increasingly important because due to the ever-widening role of the mass media in our society, students need to be informed and knowledgeable so that they can decode both wanted and unwanted communicated message

All prospective teacher educators in this multi-dimensional information age need to develop and transform instructional methods by integrating technology and web-based activities. As a teacher educator, it is important that I model instructional methods and develop activities in the classroom which centers on students to rethink how their subject/content area can be taught in the future.

The Design

According to Dodge, developer of the WebQuest strategy, the World Wide Web has become a popular wide ranging method for students to browse for factual information, online graphics, cyber communication, and global awareness. Using the Web "can revolutionize student learning." (Dodge, 2002) "WebQuests were designed to address the dilemma of using progressive learning theories, such as, constructivism, authentic assessment, cooperative learning, and scaffolding by integrating them together for effective teaching practices into one integrated student activity." (Dodge, 2002)

WebQuests engage students curiosity and often increase their motivation to learn to make conceptual connections that are related for example to a particular topic, theme, or problematic situation. Depending on how the WebQuest is designed by the teacher, students may need to respond to real world problems, confront issues, or work cooperatively with peers. (Dodge, 2002) The primary goal of using WebQuests as an instructional and learning tool is to engage students in higher order thinking skills. A good website to use as a framework for the development of the WebQuest is located at http://webquest.sdsu.edu. Included in that website are the six elements necessary for designing and formatting the structure of the WebQuest. They are the following:

1. Introduction
2. Task

BEST COPY AVAILABLE

3. Information sources
4. Process
5. Guidance
6. Conclusion

The website is particularly good because it defines the six elements needed to create the WebQuest in addition the site provides great examples of short and long term WebQuests for diverse susbject areas and grade levels.
http://www-bioc.rice.edu/precollege/k12resources/webquest/links.html (Marty Daniel, Oct. 10, 2001)

Once familiar with the construction of the WebQuest and the situation or scenario for the basic framework for the students to investigate is planned, a web editor or software needs to be chosen. One of the more sophisticated and highly recommended web editors available is Macromedia's Dreamweaver. The ability to design in layout view is a powerful feature for creating a web page because it is visually stimulating for the designer and because writing code or being a programmer is not the major factor in the overall creation. Dreamweaver does have a valuable function that allows for both views to be observed, code and design.

Another aspect to Macromedia's web editing software is the easy integration with Fireworks and Flash. The graphics, images, or video the designer may want to include is made possible with Macromedia's software packages that integrate seamlessly with one another.

Conclusions

The traditional definition of literacy has referred only to the reading and writing of verbal information. However, in today's world the concept of literacy assumes a much broader meaning in interpretation. "The term visual literacy refers to the learned ability to interpret visual messages accurately and to create such messages" (Henrich, 1996).

This paper had two primary purposes. The first purpose was to review current research related to visual learning and learning theory and to discuss the resulting critical pedagogical implications within teacher education methodology and technology courses. The second was to describe the design of WebQuests as a learning activity so that teacher education students will learn the importance of integrating technology with instructional use in their classrooms as a web-based instructional tool.

The created learning experiences which are first-hand, which are of interest, and which incorporate the students' prior experience and knowledge are engaging visual literacy skills that are strengthened by using a multimedia approach to learning. WebQuests add to the instructional and learning environment for the student because of the non-traditional approach to teaching as well as encouraging students to use higher order thinking skills to achieve the task.

Teacher educators, in their technology and methodology courses, should take a leadership role in the use of computer technology and media. Such multimedia approaches, as the WebQuest, can contribute to visually-oriented thought-provoking lessons. The design of instructional technological lessons identifies teacher educators as significantly transforming their own teaching in the classroom, through reflection, action, and the recognition that, indeed, a picture is sometimes worth a thousand words.

Sustaining Instructional Design Strategies to Enhance E-learning Among Learners at Open University Malaysia

Mustafa Md. Hanafiah
Associate Professor Dr. Abtar Kaur
Center for Instructional Design and Technology
Open University Malaysia
Malaysia
mustafa1@hotmail.com
abtar@pc.jaring.my

Abstract: The OU Malaysia views the use of advance technologies, especially e-learning as important as the University espouses a life-long learning culture with the intention to produce knowledge workers. This paper will showcase how the implementation of e-learning efforts in OU Malaysia through three methodologies: providing basic information, providing multimedia content and conducting online interactions. These efforts are in use to cater the different needs and expectations of the learners. This paper also explores on the various attributes in WebCT that are exploited to create a culture of e-learning. The e-learning design process, the adoption of the constructivist and objectivist approaches and the attributes of motivation are further described in this paper to sustain the instructional design strategies to enhance e-learning among learners at OU Malaysia.

Introduction

OU Malaysia was officially established on 10 August 2000 and our first program was offered in August of 2001. Our mission is to provide flexible, easily accessible and affordable life long learning opportunities to open and distant learners. Currently OU Malaysia has 12 undergraduate and diploma programs offered through five schools, that is School of Business & Management, Information Technology & Multimedia Communications, Education & Humanities, Science & Foundation Studies and Engineering. To support our learners we have thus far produced an estimate of 60 print-based modules and four sets of multimedia courseware (on CD ROM) and another four sets of multimedia clips for the web. To cater for all this needs, the Centre for Instructional Design and Technology was set up on January 1 2002. Its main responsibility is to assist the schools develop open and distance learning materials that are used in their programs. The center has been given the task to create more e-learning materials. Thus to start the discussion on our paper, we will look at a definition of e-learning that will help keep us focused on our e-learning efforts.

According to Rosenberg (2001), e-learning refers to the use of Internet technologies to deliver a broad array of solutions that enhance knowledge and performance. It combines both the online and knowledge management attributes. Some of the success factors for e-learning includes creation of a learning culture, receiving support of leaders, creating a nurturing environment, sustaining change throughout the organization, having formal instruction but goes beyond it, is happening all the time, has intellectual capital build-up and the individual and organizational performance is increased. In creating and exhorting the elearning culture, the instructional design (ID) process employed must be sustained throughout the learning continuum. Instructional Design according to Reigeluth (1985) is 'the process of deciding which methods of instruction is best for bringing about desired changes in student knowledge and skills for a specific student population'.

E-Learning Efforts at OU Malaysia

E-Learning efforts at OU Malaysia are implemented through 3 methodologies: a) providing basic information about the course that is being offered, b) providing multimedia content and c) conducting online interactions. The purpose of this variety is to cater for as much individuality as possible in terms of learning styles, aptitudes and time constraints. WebCT is the learning system that has been adopted by OU Malaysia and most of the e content is uploaded into the WebCT.

Providing Basic Information

Basic information consists of putting up course information such as syllabus, course objectives, readings, relevant websites and announcements. In OU Malaysia, e-executives carry out this function for those courses where faculty is not permanently with us. For those faculty which are permanently with OU Malaysia, they upload the information on their own.

Providing Multimedia Content

Multimedia content consists of two types: courseware and stand-alone multimedia clips. Courseware is created for those subjects that are difficult to understand and need a lot more e-support. The courseware is normally loaded onto CDROM. With courseware, the learner is allowed to practice a lot more and feedback is given to help the learner attain learning objectives. Courseware also consists of problem-solving strategies whereby the learner is able to immediately check his/her understanding. Stand-alone clips are normally loaded into the WebCT and the purpose of the stand-alone multimedia clips is to allow the learner to view/listen to it and then discuss the issue related to the clip using the online discussion board in WebCT. A team of experts consisting of multimedia programmers, graphics artist, animators and audio and video specialist creates the multimedia content. The content is first visualized and designed by a team of instructional designers and subject-matter experts. In the process of developing courseware, Gagne's Nine Events of Instruction are adopted by OU Malaysia. Gagne (1992) suggests that learning tasks for intellectual skills can be organized in a hierarchy according to complexity: stimulus recognition, response generation, procedure following, use of terminology, discriminations, concept formation, rule application, and problem solving. The primary significance of the hierarchy is to identify prerequisites that should be completed to facilitate learning at each level. Prerequisites are identified by doing a task analysis of a learning task. Learning hierarchies provide a basis for the sequencing of instruction.

Conducting Online Interactions

Online interactions are crucial in e-Learning efforts especially for open and distance learners as these interactions allow them to discuss shared experiences, which may otherwise be lacking. Online interactions are conducted via the WebCT learning system. Two of the most popular interactions are the email system and the online discussion board. The online moderator is the face-to-face tutor who meets the students once a fortnight at OU Malaysia's selected learning centers. Each online moderator has between 20-25 students. The online moderator has two important roles to play. One, is to answer student queries related to content. For this the students are advised to use the email. The other role is to moderate online discussions related to the content under study. As each subject is divided into 5 study units, the discussion is designed in such a way that, every two weeks, there is a discussion on one of the units. In this way, issues related to the subject is covered quite adequately.

According to the official WebCT website, WebCT has five attributes which can be applied to the innovation of technology in our university. The attributes are relative advantage, compatibility, complexity, trialability, and observability. The table below describes the five attributes. These attributes also contribute to sustaining of instructional strategies to enhance e-learning among learners in OU Malaysia and are elaborated in the section below.

Attribute	WebCT as innovation
Relative Advantage	• Automated marking of tests (multiple choice, short answer, matching and calculated questions) • Easy course administration • Communication (synchoronous and asynchoronous) between lecturer-students and students-students
Compatibility	WebCT is used for both residential (via the Intranet) and distance (via the Web education)
Complexity	WebCT is very user friendly and lecturers/tutors find it easy to use
Trialability	Lecturers/tutors can choose which WebCT functions they want to use, e.g. • Provide access for students to the current teaching material, study guides in the form of text • Communication via the Bulletin Board, E-mail, Chat rooms, • Testing which is graded by the computer and the grades are statistically processed • Course management, e.g. the student class list, student tracking
Observability	• Any function which the lecturer/tutor wants to use, is

	immediately available to view

Table 1: WebCT attributes that sustain instructional design strategies.

E-learning Design Process

According to Shank (2002), the key step in the e-learning design process is the creation of the plan for "interaction design". A series of criterion are considered before embarking on the plan: a) To determine what kind of courseware to create in the first place b) The size of the content to be developed c) The kinds of activities it should cover d) The kinds of coaching and support should it include.

The steps taken to determine concretely what needs to be taught with the solution being expressed in a specific work product are specification of teaching points, design theme, project timeline, prototype, production plan, implementation review, and functional specification.

The first activity is to gather data on what the specific need is. To get teaching points, experts and practitioners are interviewed. Teaching points are a refinement of information gathered during weeks of research and interviews. The goals of the course are to be described, and written documentation must be examined. In order to make an impact on performance when teaching, one needs to identify impact behaviors that will have the greatest effect on learners' performance and success on the job.

In determining a design theme the development team essentially chooses certain design architectures and past project experience as a style of interaction to use. A general approach 'hypothesis-driven investigation' is then adapted to assist in the designing of theme. This also involves in the planning out and dividing the design into tasks or activities and the time spent for each activities or tasks.

Before a task is designed it is structured by choosing a sample problem which is taken from a book. A learner's input is taken into the design process by having some learners work the problem using the books with the involvement of the tutors. A graphical representation of a design is done at this stage. A simple checklist is created in the forms of bulleted lists as a specific sense of how the core task is to be structured in the content.

At the production stage it describes what to be taught and how we plan to teach it. There are several decisions yet to be made as the design is structured - How will the details of the interaction be staged? What specific materials will be required to implement the interaction? How will the specific decisions the user makes be structured? How will the user be led to generalize from the specific scenario to the overall task?

After decisions have been made a walkthrough using a simple template is created. This creation is actively done by the design team members, to subject matter experts and in some cases, a representative of the user group. The design team and subject matter experts at the implementation review stage pose several review questions such as: a) Will this be an effective design? and b) How much effort will it take to create?

The final step of the e-learning instructional design process is to convert the walkthroughs into an overall learning system to the users. This also involves getting feedback from the learners and deciding on the solutions to the feedback. Adjustments are then made to improve and also to make the development of e content a cost-benefit content.

Sustaining the Instructional Design

Instructional design of e-learning is sustained by adopting a constructivist as well as an objectivist approach to learning. This is crucial as open and distance learners at OU Malaysia come from various backgrounds, experiences, and learning abilities. Constructivist learning strategies will suit the more advance learners, those who are in-charge of their learning and are ready to move forward. On the other hand, students who need to be lead, coached and monitored closely, may use the multimedia courseware to help them attain their learning needs according to their styles. These students may also use more of the emailing system to take advantage of the one-to-one coaching. However, this does not mean that they stay completely away from the online discussions. In fact online moderators are trained to identify learners who are not very active and coerce them to join the discussions. Instructional design of e-learning is also sustained when students are encouraged to contribute discussion topics for online discussion. In this manner, the student curricula is also met.

In a more physical sense, instructional design of e-Learning is sustained by providing students with computer facilities at OU Malaysia's learning centers. This is especially crucial in remote areas especially on the Borneo Island where students do not have ready access to Internet and computers.

According to Moshinskie (cf Rossett, 2002), organizations implementing e-learning projects are facing high attrition rates. During the online course, several strategies can be adapted to create and maintain motivation. These include a) maintain a conducive environment – is related to how learner is influenced by environment factors, people support, learning design strategy, and technology accessibility, b) proper chunk of information – this includes review of pre-requisites, an overview of objectives, interactive presentation of materials, job-related exercise, and a summary, c) build on the familiar- interest is build on by incorporate learners' beliefs and examples, d) vary the stimulus – vary information presentation by using audio, video, and animations, e) provide human touch – chat rooms, email, electronic office hours, video streaming and online mentoring can supply the human touch not only from tutors, also from fellow learners.

Future Plans

With the increased number of students using the WebCT, OU Malaysia has set an incredible pressure on the infrastructure, and more specifically on the availability of computers for our remote students. With the growing number of our Learner Support Centers in Malaysia it is hoped that the involvement of learners with technology will immensely improve their knowledge acquiring capabilities. This will ensure the implementation of WebCT or alternative learning system as part of a broader strategy to guarantee the creation of an e-learning environment. What we are therefore seeing as emerging is an integrated approach to sustaining instructional design strategies to enhance rich e-learning experiences in the flexible and affordable environment.

A New Paradigm For OnLine Science Laboratory Learning *Environments*

Gerald W. Meisner, Physics Dept., UNC Greensboro, US, jm@curie.uncg.edu

Harol Hoffman, Physics Dept., UNC Greensboro, US, hh@curie.uncg.edu

Abstract Robust online courses in the sciences must be based on: (1) sound, research–based pedagogy, (2) rich laboratory environments with skills and operational knowledge transferable to the wet lab, (3) a paradigm that is economically scalable. LAAPhysics courseware meets these challenges in the distance-learning field, using server/client technologies to develop and build a complete online physics laboratory learning environment comprised of equipment and instrument objects and interactive curriculum modules. Client/server data includes dialog (guide agent/tutor and student), white board discussions with virtual peers, assessment and capstone investigations. Complete portfolios of student performance are generated, permitting individual and aggregate analyses not only of conceptual understanding but also of peer to peer interactions and student understanding of various representations of experimental data.

LAAPhysics courseware is being authored to provide rich laboratory-based learning environments in the sciences for those unable to obtain such experiences in traditional college and secondary school settings. One problem the science education research community faces is the lack of data on the effectiveness of good online science laboratories. The reason for that lack of data is that no one has solved the problem of how to successfully port the science laboratory to a meaningful online environment. Without good online laboratories, we lack the necessary tools to conduct basic research on student learning in these settings. This is a recipe for a closed loop. To date, there has been no sustained and successful effort to bring together experts in content, technology, design and discipline-based education research to address these two interrelated problems. LAAPhysics uses internet-based technologies and physics education research results to create pedagogically sound teaching and learning laboratory online courseware environments. This approach will increase opportunities for individuals who currently lack them and transform the current limitations imposed by traditional classroom settings. It will also make available to pre-service and in-service teachers a research based 'online textbook' which can both increase their content knowledge and influence the way in which the discipline can and should be taught.

The LAAPhysics *system* consists of a number of innovative subsystems, which are now in various degrees of completion. All are in at least alpha stage, with beta testing of selected introductory physics 'tutorials' incorporating many of these subsystems to start during the fall of 2002. We are:

- developing open-ended 3D laboratories for the physical sciences that permit exploratory student investigations in which students are interactively engaged with their environments of space, equipment, instruments and data analysis tools. These laboratories will use research-based guided inquiry pedagogies from the science disciplines (such as *Workshop Physics*, the *Modeling Method*, and *Physics By Inquiry)* along with the most appropriate current computer technologies. A virtual tutor will guide students, as would an expert modeler, in, say, Hestenes' Modeling Workshop. We are initially authoring in Mac OS X, with Windows XP to follow.
- using a research model pedagogy to script interactive and guided laboratory-based tutorials in physics, chemistry and astronomy for students of diverse populations in diverse settings. LAAPhysics permits students to experience the scientific investigation paradigm in the context of a guided learning

experience, with branching logic enabling faculty to accommodate students of various backgrounds and levels of understanding.

- assessing student content understanding within the tutorial settings under varying conditions. Students are exposed to both higher-level concepts/tasks in which they deploy their developed models in novel situations, and lower level tasks in which they learn how to use instruments and equipment, or how to identify dependent and independent variables in an experimental investigation. Assessment and evaluation (A&E) questions are currently being authored which go beyond the common algorithmic questions at the 'end of the chapter'. Online environments permit a richness of A&E not possible with hard copy texts, provided appropriate courseware tools are authored for faculty and student to use. We have authored a variety of tools which permit faculty access to instantaneous qualitative A&E grading tools hitherto lacking: LAAPgraph, LAAPAnalysis, LAAPVector and LAAPMotionMap. These are being beta tested in the coming months. As with all online developments, midcourse corrections can be easily and quickly executed. The extensibility of the LAAPhysics approach, along with authoring tools we are developing, will permit a community of developers to quickly emerge, both here and in other countries.

LAAPhysics will not be an encyclopedia of all possible subject matter, which could be discussed, in an introductory, algebra-based course. We will author those which are most appropriate for constraints imposed by pedagogy, medium, funding and 'less is more' philosophy.

LAAPhysics uses selected IT tools, current advances in cognitive science, pedagogy research, and user interface design considerations from both the scientific and the entertainment sectors. From this array, LAAPhysics is developing an integrated software package composed of the following modularized interconnected components:

- a Physical Reality Engine (PRE)©™ that re-creates real-world phenomena in a simulated 3D environment. The open-ended laboratory workspace will contain virtual laboratory equipment and apparatus objects, the parameters of which can be varied by the user in an experimental setting. The open-ended nature of the lab space will provide enhanced environments suitable for visualizing abstract concepts, and will allow users (students and faculty) to employ the environment in unlimited creative ways;
- an Interactive Engagement System (IES)©™ that serves as the central management system of the application. The IES provides interactive content to the learner within a collaborative learning environment where students work together asynchronously with 'virtual peers' guided by a virtual tutor/guide agent. The IES monitors student progress and dynamically responds to student input with contextual modifications that individualize instruction. Through the script branching features, the IES thus guides the learner through appropriate sections and activities within each learning module, providing remedial experiences where needed;
- a System Tools Package (STP) that contains Learner Tools (LT) and Authoring Tools (AT). Each tool is a stand-alone component that can interface with various other components of the application. LT are student research tools that include graphing and data analysis tools. AT include an XML-based editor and development tools that will enable faculty to modify and extend either the engine environment or the content environment with minimal programming skill or knowledge;
- an Information Storage System (ISS) that sorts and stores student and course data on a remote server and furnishes that information to the IES for display to the user (student and/or faculty).

We are in the early stages of:

- developing research methodology on the effectiveness of LAAPhysics learning approach compared to traditional methods of teaching. We will assess both content knowledge (using accepted instruments) and laboratory skills of students who learn in the online environment, comparing this to those students from various conventional learning situations. .
- developing research methodology on the interface between student and machine in this interactive environment. Student interaction, such as use of graphs, tool selection, mouse actions, time on task and data analysis strategies, will be stored in databases that can serve as a research base for understanding important user interface and design issues.

- investigating techniques to enable those students with visual impairments to use and benefit from LAAPhysics.

The beneficiaries of the LAAPhysics approach to online laboratory based courses are:

- Students: Underrepresented populations: inner city minorities, native Americans, and others missing from the MSET mix; whose labs are inadequate or missing: from poor regions of the country, economically strapped community colleges, under-funded high schools, and colleges with inadequate space; those with scheduling difficulties due to work, family or geographic location; those who are ill, injured or who have disabilities.
- Faculty: who are interested in conducting research on student learning in online environments; who are interested in conducting research on student conceptual learning by means of a detailed LAAPhysics portfolio which is automatically created for each student; who want the option of "customizing" course material, and those who want to adopt the role of mentor rather than dispenser of information.
- Institutions: where economic realities make it unfeasible to pay for the high cost of laboratory space; where there is a conflict between lab space and other space demands; where the number of well trained lab instructors is limited; where home schools or struggling charter schools are used.
- Distance Learning Community: where the current absence of scientific laboratory work places severe constraints on distance learning.

LAAPhysics is a generalized simulated 3D laboratory learning environment that models an open-ended laboratory and thus facilitates the transfer of skills and experience from the virtual program space to real world classrooms and laboratories. The system allows students the freedom to make errors, which will be corrected through a further dialog between mentor (written script) and student. The modifiable software package is modularized and designed to provide an extensible interactive online learning environment for authoring introductory laboratory courses in physics (now), astronomy, and chemistry (in the future) and for conducting research on student learning in web-based environments. Our claim is not that the LAAPhysics is better than *in situ* guided inquiry laboratory based courses. Rather, LAAPhysics addresses those instructional situations where *in situ* introductory courses are less than ideal: those that are based on lectures alone, or where students have limited access to laboratories outside of scheduled class time, and/or where students may lack the apparatus and instruments that have been central to scientific investigations of the 20th century.

The Use of Course Mentoring Websites for Collaborative Curriculum Design and to Support Adjunct Faculty Teaching For Lesley University

By Dr. Linda Mensing Triplett Ed.D.
And
James A.J. Triplett M.S.

April 8, 2002

Abstract

Course mentoring websites (CMW's) have proven to be powerful vehicles for providing support and professional development to adjunct faculty teaching required courses for the Technology In Education Department at Lesley University. Adjunct faculty teach courses in many different locations across the United States, using a variety of course delivery models (delivery models include face-to-face courses that meet once a week, weekend courses, online courses, and hybrid combinations of online and face to face instruction). CMW's provide adjunct faculty with access to experienced professors who serve as online course mentors. CMW's are accessible to all the faculty members and furnish a medium for defining and publishing course standards, for giving faculty access to high quality instructional resources, and for maintaining consistency in the delivery of required courses. In addition, CMW's foster a sense of intellectual community among the faculty teaching each course. The goal is for each faculty member to consider themselves an active participant in an ongoing, online curriculum development process. CMW's provide the online context for communication and collaborative course development, and they can be constantly adapted to changing needs, to advancing technologies, and to the realities of diverse teaching environments.

Experienced faculty serving as course mentors establish and are responsible for the continued development of each CMW. The faculty mentor communicates and collaborates with all other faculty members teaching the same course, to gather resources in an ongoing way, and for the purpose of continually improving the CMW.

CMW's are organized to provide faculty with easy access to a variety of resources. Lists of prerequisite skills that students taking the course will need in order to participate in a meaningful way are made available, as is a set of resources that can be provided to students who feel they need to work on these prerequisite skills. The framework being used for online curriculum development requires that each course have a list of overarching goals related to NCATE/ISTE standards, and that each of these overarching goals be accompanied by an essential question and connected unit goals. Each unit goal has a set of suggested activities which can support the achievement of that goal. These sample activities can be used by faculty for creating course syllabi. Unit goals also have a set of outcomes and/or culminating performances that will help both the instructor and the students determine if goals have been achieved. Performance assessments accompany each activity (i.e. a set of scoring rubrics). The website lists software and technologies that are to be used in the course and a set of technical skills that will be learned. The website also includes an updated set of sample syllabi from adjunct faculty, as well as the

URL's of course websites that have been developed by faculty and are used for teaching the course.

CMW's are built upon technologies that provide access to information and resources, and support both communication and collaboration. Each CMW includes technical tools for collaboration between faculty. These tools are designed so that it is easy to create and continually modify curriculum. Tools include message boards and discussion forums, chat rooms, and visual cues as to when and who last updated a particular part of the course. Publication space is provided for all faculty. Curriculum materials and resources, such as worksheets and handouts can be attached, and these can be made available for various computing platforms (i.e. Mac and PC). Links to web pages are provided, as are NCATE/ISTE standards pages and appropriate help for integrating these standards into the course. Each CMW has built-in support for using technologies to enhance teaching of the course, including models and examples of technology integration in the curriculum. Models of effective pedagogical methods and principles are also provided. Examples of exemplary student work on major projects are included in each CMW, with accompanying performance assessments.

Faculty responsible for developing CMW's recognized the need to develop online course content in a production mode similar to computer software programming. Thus is was determined that CMW's would be designed in "course content modules". The Sharable Course Object Reference Model (SCORM) under development by Advanced Distributed Learning Network (ADL) provided an example and standards for construction of course content modules. Reusable course content modules are appealing because - although Lesley University is a traditional academic institution where individual faculty offer learning experiences that are unique and result from their own expertise and creativity - the productivity, richness, and high degree of maintainability of "course content modules" and the ease of sharing these among faculty members via web technologies has begun to change traditional academic thinking. Economic and competitive pressures, as well as rapid expansion of programs within the Technology In Education Department have also driven online development of course content modules.

Initial CMW design efforts were built on the Blackboard Course Management System becaus it facilitated web delivery while providing as set of integrated tools for communication, access to publishing spaces for faculty, and resources for measuring course outcomes. However, Blackboard uses a proprietary approach for constructing course modules, as well as for importin and exporting course content. Its template oriented framework did not provide the necessary flexibility or allow for development of course content modules that could be easily utilized by faculty working in a variety of other web formats.

For these reasons, it has been necessary to move away from the use of a Course Management System like Blackboard for this project and to establish technical standards that would permit interoperability and free exchange of content developed in various software packages. The recent development and deployment of tools for building websites and web-based information systems that are usable at all levels of expertise gives Lesley University the opportunity to builds it's systems on Internet-standard technologies using commonly available free or inexpensive tools.

Starting with a standard shared-server Unix-based website, one can layer open-source software systems to provide the desired functionality. Basic requirements for a CMW include easy upload and download using FTP or tools such as MS FrontPage or Macromedia Dreamweaver; a dynamic webpage creation environment using a scripting language such as PHP; and an SQL database such as MySQL accessible from that scripting environment. Because this platform is commonly used throughout the Internet, it is easy to build a user environment with sophisticated features like user-personalization, discussion forums, and individual upload capabilities, using freely-available software packages. For their course development work, faculty are able to use inexpensive commercial packages like FrontPage or Dreamweaver, or free tools such as Arachnophilia or CuteHTML.

Learning Cubes: A Model for Online Education

William P. Messier
Coordinator, Multimedia Management and Production
McLennan Community College, Waco, TX, United States
wpm@mcc.cc.tx.us

Abstract: This paper describes how a faculty development project was designed for the World Wide Web. The paper also describes interactions that took place between faculty to illustrate how collaborative learning and problem solving can be facilitated and implemented by the web. The project assignment content focused on instructors (students) being immersed in an authentic learning environment. The students actually experienced a form of technology based learning while undertaking specific tasks. The paper concludes with some pedagogical discussion about the use of cooperative learning as a teaching strategy for online education.

Introduction

Online learning is a relatively youthful field, which is still being classified as a discipline. As Administration and faculty members struggle with decisions about how to structure online courses for collaborative, cooperative learning, faculty perspectives of successful strategies can provide valuable insights for decision-making. Few studies have been conducted that examine the impact of the collaborative teaching/learning strategies in the distance-education setting (Hardwick, 2000). This paper presents general research findings pertaining to collaboration in online learning along with personal insights into what makes a project-based online assignment successful as a collaborative learning experience.

While online learning offers administrators, faculty, and students many advantages over traditional campus-based learning, problems do exist. Attrition is one such problem for online learners. Attrition is brought about in large part by a sense of isolation (Adelskold, Aleklett, Axelsson, & Blomgren, 1999). One teaching/learning strategy, which can improve this sense of isolation, is cooperative or collaborative learning. Collaborative learning involves students in social communication, as groups work together to discover knowledge, think critically, communicate effectively, reflect, and solve problems. Social interaction among learners plays an important part in the learning process, in fact, it can have a significant impact on learning outcomes. (Jonassen, et. al. 1995, Eastmond and Ziegahn 1995, Berge 1995). Students in online education programs, though separated spatially, can gain a sense of community as they distribute and simplify ideas, actively contribute to a team, and cooperatively solve problems (Cecez-Kecmanovic & Webb, 2000).

With progress in telecommunications and computer technologies, it is now possible to offer collaborative learning experiences in a cost-effective way. In the past, collaborative approaches to distance learning were limited by the cost and sophistication of the technology. Recent advances in technology coincide with a general shift in educational theory to a collaborative origin of learning, which recognizes the learner's need to share control and assume responsibility for problem solving in the context of a peer group (Anderson & Garrison, 1998). Collaborative learning is an outcome of cooperative learning, in that students must develop cooperative learning skills in order to use them in self-directed, high-performing teams. These collaborative groups conduct free investigation and members jointly discover and solve problems. Success in cooperative learning is grounded in the skills students develop within the context of the academic organization provided by the facilitator/instructor. More importantly, in distance learning, students must possess or develop the technical skills necessary for online communication, as well as acquire and practice social skills necessary for collaboration (Kemery, 2000). Cooperative learning involves requiring individuals be accountable so that each participant does a fair share. It involves effective cooperative social skills, effective and appropriate communication skills to bring the task to completion. Research shows that such cooperative learning practices lead to more efficient and effective processing, increased achievement, positive relationships among students, and efficient exchange of information (Johnson, Johnson & Smith, 1997).

Overview of the Model

Since collaborative learning is an outcome of cooperative learning, learning cubes is a product of both teaching strategies. Learning cubes is another name for peer learning and teaching, peer tutoring or team learning. The major difference between these learning strategies and leaning cubes is who is delivering and the amount of information delivered to the student at one time. With learning cubes one student will take responsibility for a certain prescribed amount of information and teach it to a small assigned group of students. This prescribed amount of Information disseminated by the group will be small, challenging, and productive. Prescribed information can be layered assignment to assignment allowing connections of previous taught material to be made while threading new ideas or skills to be learned from the group. Group size for the learning cube is usually small between two or three students. This size increases effective interaction between students while extending the learning process. Some positive interdependence is built in to the experience so that members need one another to accomplish common goals of constructing knowledge. Learning cube, team learning, and peer tutoring works best for some students and it may not work well for all but in most cases students increase learning while not hindering the learning of others (McKeachie, 2002, Larson, 1984). Students become active partners in the learning process and may learn effectively from interacting with their peers. Instructors may need to spend more of their time in the role of facilitator, organizing students, managing students, and helping students work together effectively.

BEST COPY AVAILABLE

Within a faculty development classroom, nine newly hired McLennan Community College (MCC) educators participated in an online collaborative project-based assignment. This faculty development was mandatory for all newly hired instructors. The educators taught in various fields of study. All educators were given two preliminary workshops using Blackboard, the e-learning course management system software.

As students, the instructors were given two weeks to complete the assignment. As learners via the web, the instructors could interact with one another from different geographical locations either in synchronous (real time) or asynchronous (delayed) mode via text-based communication for the purpose of dialogue. All members of the group had to complete the activities assigned. For assessment purposes, students were required to demonstrate newly learned skills in two pieces of work: 1. after learning how to create a web page from a Word document, each student must create a HTML document reflecting the pros and cons of cooperative learning, and 2. another HTML document reflecting upon items given on their pre-survey.

Model Structure

Within Blackboard the interface structure was designed for ease of use. There were eight categories of interactive buttons designed on the left side of each web page. The categories were in the following order: 1. ***Announcements*** – this category welcomed students online, reinforced what the emphasis of the activity is about, gave minor reminders about the use of Blackboard and the assignment, allowed students to take a pre-survey, and gave day and times the assignment help desk could be accessed for technical support. 2. ***Course Information*** – this category gave clear and precise responsibilities for the groups teachers and students. 3. ***Course Documents*** – this category gave clear and precise instructions for downloading a digital streamed video movie. 4. ***Assignments*** – this category allowed students to take a pre-survey, study a streamed movie, apply new knowledge learned to a simple activity, and teach this new knowledge to the group. 5. ***Books*** – this category gave references as books and websites about cooperative, collaborative, and team learning. 6. ***Communication*** – the communication category gave students access to e-mail or a real time virtual chat room. 7. ***Virtual Chat*** – this category allowed students to browse the archives for a previous virtual chat room sessions as well as access to the virtual chat room. 8. ***External Links*** – finally, this category allowed students to access educational data bases like ERIC.

As group members mastered making a web page using Word, each member of the group had to demonstrate new knowledge by completing their own HTML documents. Completed assignments were then forwarded to an email address on the assignments web page.

Pre-Activity Assessment

For feedback purposes, each member of the group was asked to participate anonymously in a pre-activity assessment. The survey was designed to stimulate thoughts concerning the topics of cooperative learning. All survey questions were designed using Blackboards management system. At the end of the required assignment, this survey will be used as a reflective evaluation. The following questions are from this pre-activity assessment: 1. Do you feel that high quality learning can take place without going to a traditional educational facility? Why or why not? 2. Do you like the idea of sharing your work, life and educational experiences as part of the learning process? If your answer is yes or no explain why? 3. Do you think it is possible for increased learning to take place when work/knowledge/life experiences are shared with peers? Why or why not? 4. Do you accept the value of facilitated learning as an advantage over the more traditional lecture based learning process? Why? 5. Have you incorporated cooperative learning into instructional methods? If so, how?

Faculty Interaction: Pre-Activity Assessment

To **question one**, do you feel that high quality learning can take place without going to a traditional educational facility? Most faculty members felt that high quality learning outside the traditional educational facility happens all the time such as people learning at the work place, reading/learning at home, or people learning about a new sport. Many instructors still feel that there is distinct value in face-to-face communication with students and teachers. **Question two**, do you like the idea of sharing your work, life and educational experiences as part of the learning process, most instructors commented positively? All instructors felt that their rich learning experiences should be shared with their students. **Question three** asked, do you think it is possible for increased learning to take place when work/knowledge/life experiences are shared with peers? All respondents had positive statements about this question. **Question four** inquired, do you accept the value of facilitated learning as an advantage over the more traditional lecture based learning process? The comments for this question were mixed positively and negatively. For the most part, many instructors felt that it would depend on the circumstances. **Question 5** asked, have you incorporated cooperative learning into instructional methods? This question also got mixed responses. Five instructors answered positively saying that they have used this teaching strategy before. Some faculty used cooperative learning a little, while others did not use it all for instruction.

Faculty Interaction: Post Survey

At the end of the two weeks, all instructors involved in the project-based assignment were given a simple post survey. The post survey primary contained open-ended questions about the direct impact this assignment had on the users as teachers. The questions were: 1. How were you actively engaged? 2. What aspect of the project-based assignment will you immediate incorporate into your teaching? 3. What was missing that would make this project-based assignment more valuable to you?

BEST COPY AVAILABLE

Most instructors completed the online collaborative project-based assignment within two weeks. Instructors who had experience using computers or the software program Blackboard had finished the assignment early. Faculty who had limited computer experience took the full two weeks to complete. Although the participants did not choose their own group members their post survey answers indicated that they were actively engaged in the project-based assignment. This was primarily because of the pre-activity assessment, the watching of the streamed tutorial movie, and the engagement of making a HTML document from within a Word document.

Instructors also commented on what aspect of the project-based assignment would they immediately incorporate into their teaching. Most commented positively.

Instructors also commented on what was missing that would make this project-based assignment more valuable to them. One instructor commented, "perhaps a little more detail on the value of cooperative and its integration to be used in web pages." Two instructors said, "I would have liked to learn this from a traditional classroom setting." While most instructors commented that nothing really stood out, a few still had problems following directions or working with the methodology. These instructors commented, "a little hard following instructions," "this was very time consuming," finally, "it was too hard to get into this."

Pedagogical Issues

Cooperative or active learning methods may not be appropriate for every institutional setting (e.g., part time students working full time). For new teachers beginning to implement cooperative strategies, the idea of using students' as instructors teaching small amounts of information may be somewhat intimidating. If you are teaching specific content or cognitive processing, each session must facilitate an environment conducive to collaboration. For learning cubes, team learning, peer tutoring to work, the groups and the content delivered must be small and effective. Further, the team project or assignment must be challenging enough to insist teamwork. Besides, challenging assignments replicate real world situations and help prepare students to be productive life-long learners.

To have effective group members, instructors should provide guidance for students on how to work successfully in collaborative teams. The social characteristic of successful teams should be clearly taught and not assumed. Successful teams will have certain member qualities. Among those sought-after qualities are an interest in other team members beyond the task at hand, the capacity to clarify and commit to goals, an open and honest evaluation of team performance, an understanding of others' perspectives, a wish to confront conflict positively, a commitment to make decisions inclusively, the valuing of individual differences, a willingness to freely contribute ideas and encourage that in other team members (Robbins & Finley, 1995). Group members play an important part in the success of the assignment. From the group's perspective, clear and distinct roles for each member can aid in the groups communications. Among group members, a clear understanding of assignments and work responsibilities can make task management easier for each student. Tasks and authority in the given areas of responsibility must be well defined. Individual team members may be given more decision-making authority in their various areas of expertise.

In planning your courseware design for online education the instructor must provided the following: 1. provide effective technology workshops for students if new hardware and software will be used in the session 2. provide a technology help desk with appropriate days and times users can receive help 3. provide students purposeful asynchronous and synchronous help sessions 4. provide useful creative chat sessions for office hours with appropriate days and times. Additionally, flexibility in meeting assignment requirements facilitates students to develop ownership of the assignment, aids in the development of critical thinking and problem solving skills, imparts room for originality, and encourages a sense of group individuality and unity. Providing a plan for group formation is imperative for team success and cannot be underestimated. Helping students choose team members intelligently will aid in the formation of group member roles, allow members of the group to fill needed areas of expertise, and provide a solid foundation for shared esteem among group members.

In a collaborative group effort, certain individuals may be chosen as project manager for the purpose of setting task deadlines or resolving conflicts of opinion. Once set, group members should hold each other responsible for meeting deadlines with weekly meetings and encouragement. In every group effort there will be differences of opinions. Decisions must be based on ideas and not on personalities.

Conclusion

This brief paper has provided insights into the nature of cooperative learning as a teaching strategy for online education. Online collaborative project-based assignments can be a rewarding experience if certain factors are incorporated into the teaching strategy. A skillful facilitator, capable of balancing guidance with flexibility is one crucial factor. Another is a group with the skills, both technical and social, to truly collaborate the learning process. When those crucial factors as well as other pedagogical issues come together in a learning setting, collaborative online assignments can result in a product exceeding the expectations of the teacher. It is hoped that a useful model will be developed to enable instructors to use online software management systems like Blackboard. It is also hoped that the pedagogical issues of teaching online discussed throughout this paper will be used by educators. As higher education institutions seek to make decisions about how to structure online courses for collaborative, cooperative learning, it is hoped that administrators and faculty alike can gain valuable perspectives and insights for the decision process.

Abstract: Distance learning techniques developed according to previously existing Internet models do not always produce educational tools that serve students well. Rather than adhere to the "supermarket" templates typically used by commercial Web sites seeking to attract and dazzle consumers, which require users to master the rules of navigating among a range of global options, I have found that a *linear* model based on email communication conventions better addresses students' needs. The complex challenges associated with learning public relations writing via the Internet are made simpler through the use of relatively low-tech online presentations. The emphasis is on creating relationships with and providing prompt feedback to students, and sharing information among students, to better replicate many successful pedagogical techniques of the classroom. I hope that my experience teaching writing courses in the classroom and online simultaneously will provide valuable comparisons of useful techniques for teachers in other disciplines.

Introduction

I teach public relations writing. In today's marketplace of ideas, the craft of public relations writing is an important tool for effective advocacy. Public relations writing is often more than a necessary skill in the global arena of contesting ideas – in many cases it *is* the arena itself.

Public relations writing is a complex process involving three sets of skills: research and organization ("pre-writing"); the writing itself, necessarily the product of an individual talent; and rewriting, often a consensus effort requiring a process of compromise among several interested players.

To develop these skills, students employ several styles of learning. As they are introduced to techniques of research and organization, they are acquiring and assembling information and putting it into practice, much as a physics student might. As they discover the disciplines of editing and rewriting, they are internalizing an essentially social process involving both interior and interpersonal negotiation, much as an actor or dancer might. And as they develop skills in the "actual writing," they are working individually, under the eye of a master, to perfect technique, much as a medieval crafts-guild apprentice might.

Writing as a Process

Public relations writing is made more complex by the fact that public relations writers actually serve not one but three masters – the story, the editor and the client. To tell any story, students must acquire basic writing skills; sadly, this is not a given in today's undergraduate population. By basic writing skills I mean not only the ability to develop a theme, paragraph by paragraph, but even the awareness of what constitutes a good paragraph. Second, students must learn to express themselves within the disciplines of journalistic style, a style for which most English composition classes have not prepared them. A generation ago, a general familiarity with news style was naturally acquired, through habits of newspaper reading; this is no longer the case. Third, students must learn to persuasively focus a client's message in terms that please the client, as well as in a style acceptable to news editors.

Thus the process of public relations writing implicates three sets of skills, and three different objectives for the writer. The order in which these activities unfold is ultimately not important – the professional writer will develop personal work styles out of individual preferences. But I have found that my students avoid confusion and do their best work when they acquire these skills in a certain order, advancing to the next stage only after demonstrating an understanding (though not yet mastery) of the preceding one. The details of the order are less important for my present point, than the fact that there exists an optimum order for the presentation of the elements of an education in this discipline.

Substitute Techniques

In the classroom experience, that optimum linear order is maintained in real time, by the content of each class discussion and exercise, and by attentive monitoring of students' progress. (Also important is the fact that Columbia limits each writing class to fifteen students.) Online I have had to develop substitute techniques.

Objective assessment indicates that my in-class students progress from mediocre to very good over the course of each fifteen-week term, and their level of accomplishment serves as the basis by which I make evaluations of my online students. This comparison is made easier by the fact that I teach both sections simultaneously using the same syllabus; I am able to monitor, week-by-week, the progress on both sides.

When I undertook to create an online course at Columbia College Chicago, I established as a key principle that the online experience would be asynchronous and strictly online. That is, students would be able to sign on and do their coursework at any hour, independently of whether I, or other students, were online at the same time; and there would be no requirement for a personal meeting (with the possible exception of a final exam), nor would students be required to chat with me or with each other in real time. A student should be able to complete my course from a computer on the moon. My purpose was to develop a genuine distance learning system -- I had already long been providing online enhancements for my in-class students, and did not intend merely to shift from a preponderance of classroom instruction to a preponderance of online instruction.

The other guiding principle was that my online students should be afforded all the advantages that my classroom students enjoyed, though it was clear that this would call for some ingenuity in devising recipe substitutes. While my online colleagues will recognize this as an inherently impossible objective, they will also appreciate that with a little redefinition, nothing is impossible.

The three most difficult amenities to substitute were the teacher's personality in conveying information, the benefits of continual evaluation and feedback, and the students' ability to learn from other students. My success online, as well as in the classroom, I am convinced, depends upon the quality of the teacher-student relationship I am able to foster; continual feedback; and the dynamics by which students learn from other students ("If he can do that, so can I.")

Email Relationships

I began by rejecting the "supermarket" template typically used by commercial Web sites seeking to attract and dazzle consumers, which requires the user to master the rules of navigating among a range of global options. Like any teaching activity, an online course must work to engage students; but it need not "sell" them. Put bluntly, the online student is a captive audience and the combined effect of design and language can be put to the service of educating rather than capturing attention and convincing the user to keep turning the page.

I decided, instead, to build on the observation that young Internet users develop real relationships with others via email and real-time chatting; and the related fact that the easiest and most intuitive Internet activity is the use of email. My first communications with each student are personal email messages, in the week or so before classes begin. I provide general orientation, and also pose questions that require a response from students. In some cases (depending on how quickly they respond to each message) I have exchanged as many as six rounds of email before the first lesson.

Some of these email messages – and, later in the course, some email messages that complement the lesson material – are group messages, not personally composed. But from the standpoint of the student, they appear to be individually directed. I achieve this illusion without undue deception, simply by addressing the email message to my own address, with "blind" copies to the student list. I maintain my email relationships strictly in the second-person singular.

Once the student is provided with a username and password, the focus shifts to the lessons posted online. In Week One, only Lesson One is available – and not via the syllabus/lessons links (which will be activated later), but as a "Next Page" link from the introductory page of the course site. Even though the student has now been launched into the course trajectory, I continue to maintain an email correspondence – usually simple, short messages – especially when I think the student will benefit from a little prodding.

Personalization + Interactivity = Feedback

To make my system more personal, I chose to use a "stand-alone" course site, physically located on the server at Columbia College Chicago. Rather than begin at a course management Web address, students reach their lessons by clicking on a link in their email (taking them to http://prwriting.columbiacollege.net, a URL I personally own, aliased to redirect to the Columbia site). Students arrive immediately at the first page of the course. The design is crisp and clean and easily legible, uncomplicated by any row of icons leading to an array of options; above all, the Web pages are low-tech, without extraneous graphics, devoid of animated features. Each page loads quickly.

The first page is illustrated with a casual photo of the instructor, and a personal message, signed with my handwritten signature. The message is, in style, theme and content, a continuation of the email correspondence we – the student and I – have already enjoyed. Each week's lesson begins with a similar page and, of course, a fresh message introducing the work at hand.

From the outset the pages are laid out in a one-way sequence: they may be read only in one clear narrative path. In the navigation bars there are links to a variety of resources, but initially each of those links evokes only a firm but gentle admonition that these resources are not yet available. In the first week, the student advances from page to page in a strict sequence.

Lessons average about seven Web pages, of varying lengths. Every two or three pages there is provision for some interactivity – a questionnaire to complete, an interactive exercise demonstrating a principle, or a page calling for a short essay response to an online article. Every lesson also includes a quiz, which doubles as a review device. Though they are disguised as various forms of online communication, these interactive interruptions are all simple HTML forms which, when submitted, automatically generate an email response to me. By tracking these responses I am able, not only to evaluate each student's understanding of the lesson material, but also to follow his or her progress through the lesson. I know when students have signed on, and how quickly they are advancing, and I am able to email a student who is not leaving a trail, and inspire him or her to get with the program – or consider dropping the course.

Online educators are familiar with the problem of otherwise able students losing their way in an online course. My experience is that students need to be told repeatedly, while they are still able to drop the course without penalty, that an online course will make serious demands on them. I have developed a short litany of admonitions, delivered within the initial sequence of emails as well as in the introductory lesson material, to the effect that there is no shame in dropping a course you can't handle, but no excuse for falling behind once you've confirmed your commitment to the course. Online courses are flexible (study when you want), but there are deadlines (turn in assignments when I want), and late assignments are just as late for online courses as for in-class courses (or clients' expectations.) I have found that when I stress these points early, those students who remain in the course perform to higher expectations.

Another important lesson for me has been the students' need for immediate feedback. There is a tendency among online instructors to manage the workload by batching certain types of work and responding, by category, on the instructor's timetable. My system encourages me to treat my students as I would any other email correspondents. I acknowledge receipt of their assignments as soon as I notice their arrival; I address, point for point, every email message, almost always on the same day; and I edit and annotate students' assignments (see below) as soon as possible, almost always by the following day's end.

Students Learn from Students

Links on the navigation bar become effective in the second or third week, and students may then browse through a wide range of examples and other resources. After all the students' first assignments have been completed, they may take a look at how other students have solved the same problems. When I begin assigning letter grades (usually not until the fifth week of the fifteen-week course) they may study examples of real student work that earned an "A," a "C" and an "F." Though I have the capability of putting classmates' papers online, I use examples from previous semesters, rendered anonymous. In these and similar ways, I share students' work with students, without requiring them to interact with one another.

I have experimented with real-time chats among students, and a "Conference Room" where students could post asynchronous messages to one another. I have also experimented with a system whereby students could post responses to a question posed, and read one another's replies. These capabilities were derived from course management systems I had investigated. They seemed to be desirable features – until I questioned the premises of that desirability. I have not found that students were in any way assisted by these hoops through which I asked them to jump, and I have discontinued all efforts to create the illusion that students are together in a "class." In fact, I find such efforts counterproductive to the more important objective of creating a teacher-student, editor-writer relationship.

Often, during the first or second week, a student will email me asking for a further explanation of lesson material. This is a natural extension of the email relationship we have cultivated, and the request is not unreasonable. In the classroom, one way a student learns from another student is to hear a question asked and answered; both the question and the answer are educational. I should add, the question can also educate the teacher, and sometimes the emailed question will cause me to reconsider how I have presented the lesson. However, if the online student's question has already been addressed in the lesson, it is usually the case that the student is asking for private tutoring beyond the scope of the class. In such cases – and they are the norm – the students will find that their questions are answered with questions – "Look again at Lesson 2, page 2, and tell me what *you* think." – and my questions are not rhetorical: I follow up and insist on answers to questions raised by their questions. I have found that this additional demand on the student's study time gently but firmly nudges him or her toward the full use of the online material and away from an expectation of private tutoring, or other abuse of the one-on-one email relationship.

By the final weeks of each semester, students are producing drafts of press releases and other public relations writing, and I am editing and returning them as quickly as I receive them. This calls for a system of folders to keep them sorted, and a system of renaming files before sending them back. I require students to use a strict system of nomenclature – a standard prefix ("PRW"), a hyphen, their last name, another hyphen, and the assignment identifier – in both the attached filename and the "Subject" field of their email message. For example, "PRW-Smith-HeartPR" identifies a press release on "From the Heart" by Smith. After editing I simply append a hyphen and a letter grade (or, early on, an "x") to each filename, before attaching and returning it.

When I edit a student's work, I use an open file of "Notes" adjacent to the student work on my computer monitor. "Notes.doc" is a Microsoft Word document containing twenty or so "Text Box" comments representing the most frequently called-for observations and edits. I drag appropriate comments from the "Notes" file to the student's work, and always personalize at least one of them, and sometimes otherwise tweak them. I also make free use of the "Rounded Rectangular Callout," "Strikethrough," "Arrow" and "Highlight" features for my comments. I then email the marked-up assignment to them as an Microsoft Word attachment.

Conclusion

There is a consensus among online teachers I have interviewed, that unless the course is carefully managed, an online course can require significantly greater work output per student, than an in-class course. This is not surprising: there's a reason why we collect students together in one room for group work. If online education is to be a viable alternative to in-class education, the workload issues must be addressed. However, high-quality standards of online education are unsupportable if the course is simply an interactive textbook. The techniques I have developed are work-saving devices that support genuine one-on-one relationships without going overboard in the direction of private tutoring. I continue to experiment with ways to promote those relationships, without which genuine education cannot take place – and to complement the course material with the means for expeditious feedback, and ways for students to learn from other students.

"Virtualizing": A Brazilian Initiative for Upgrading Media Knowledge of K-12 Public School Teachers

Abstract: This paper describes a project-in-progress for upgrading Brazilian public school teachers' media literacy skills. The project, called "Virtualizing", is currently being applied at a municipal level, in the city of Florianópolis, Santa Catarina (Brazil), to 180 K12 teachers with generally little or no knowledge of computers and the internet. An constructivist educational design strategy was developed in partnership with the Distance Education Laboratory (LED) of the State's Federal University (UFSC), aiming at maximizing the teachers' exposure to informatics and internet technologies via the use of an online learning environment (VIAS-K). After describing the program circumstances, objectives and strategies, the authors focus one of the program's courses (AVA II), designed specifically to further demystify new media and give teachers a renewed sense of control and participation in the information society.

Virtualizing: Project Circumstances & Objectives

Reality of the Brazilian Public School System and Recent Legislation

In Brazil, there is a 2-tiered education system: private and public. While private schools in Brazil are comparable in quality to those of the North America, Public Schools at the K-12 level tend to have fewer resources, with lower teacher education levels and technology available. However, efforts have been made to improve these differences. For example, in 1997 the Brazilian Ministry of Education decreed that computers and access to the internet be issued to all public schools, under the condition that the schools present an appropriate pedagogical strategy [MEC 2001]. This has made the public schools' concerns the same those concerning all educators around the globe: how to appropriately use computers and networks in the classroom? Another law recently implemented decrees that all school teachers must have at least an undergraduate uiversity degree. At least 50% of the Brazilian school teachers will have to upgrade their skills.

This paper describes a constructivist strategy for upgrading 180 Brazilian K-12 public school teachers' skills, via demystifying computer and internet technology. The authors participated in the instructional design and system design process, aiming toward objectives and results that could be examplary for both public and private school teachers, throughout Brazil and around the globe.

Virtualizing Project Objectives

The Virtualizing project is a partnership between the Ministry of Education of the Municipality of Florianópolis and the Distance Education Laboratory (LED) of the Federal University of Santa Catarina (UFSC). The program consists of courses for 180 teachers from 19 elementary and junior high schools with computer labs. The teachers were selected from various subject areas: Language Arts, , Geography, Mathematics, Biology, etc. The principal objective of the program is to encourage, via immersion in an e-learning environment, a culture of technology use and appropriate pedagogical strategies for the municipality's public education system.

Program Resources & Strategies

VIAS Knowledge

VIAS Knowledge (VIAS-K) is an educational platform that offers a broad set of interactive models, including learning environments for users, multimedia content, tools for collaboration, support and system management. The platform unites stateof-the-art information technologies with appropriate pedagogical methodologies. It aims to attend to the growing demand for education in Brazil and is modeled toward continually improving efficiency during the learning process. [Freitas et al 2001]. VIAS-K was conceived in October of 1999. In March of 2001 it was ready to support its first users - a 1 year distance education program for 600 students (teachers from the areas of maths, chemistry, biology and physics who had not yet finished undergraduate studies).

Since many of the learners are new to computers and networks, an important aspect of the VIAS-K learning environment is its user support system. In addition to online support tools and information, every course offered via VIAS-K relies on the added support of live course tutors. The tutors help students and professors to use the technology and act as facilitators in the communication and learning process.

Another aspect of the VIAS-K platform worth highlighting is its model for accessing the system. The first screen the student accesses is a Portal of information related to the course, managed and automatically updated by administrative members (in this case, member of the Ministry of Education) through online forms allowing for the upload of text and graphics. The Portal model serves to keep the group informed as a whole, with timely and relevant information, as well as providing news to the public in general. The Portal also contains the point of login for students, professors and tutors. Upon entering a valid user ID and password, users have direct and unlimited access to course content and support tools. Fig 1. illustrates this access dynamic.

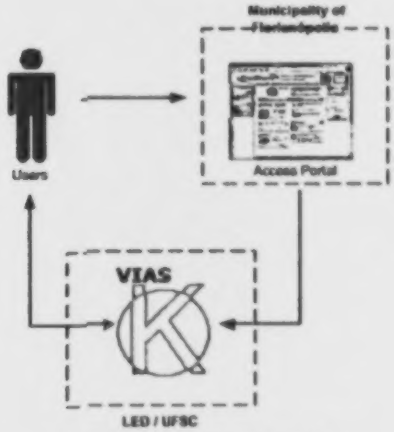

Fig 1. VIAS-K access procedure

Fig. 2 presents the VIAS-K main page and its elements: 1. navigation content tree (a graphic organization of educational content); 2. content area (once a topic is selected in the navigation content tree, it is shown in this area); 3. user identification; 4. tools (divided into 5 categories: personal tools, administrative tools, collaboration tools, support tools and on line-help); and 5.logout area.

Strategies

The 180 teachers were divided into 6 groups. Each group selected a course according to their interests / needs. The courses mixed face-to-face and on-line learning, as shown in table 1 below, during a period of 3 months (April 25 – August 30, 2002).

Group #	Courses	Total Number of Participants	Total Hours	Hours	
				F-t-F	On-line
All	Virtual Learning Environment I	180	20	14	6
1	Media and Knowledge	30	40	17	23
2	Accessibility and Technologies	30	30	9	21
3	Digital Workshop: constructing texts	30	20	6	14
4	Digital Libraries and Knowledge Management	39	40	17	23
5	Virtual Learning Environments II	30	30	9	21
6	Multimedia production technologies	30	20	6	14
Total number of Hours		**200**			
Total hours Face-to-Face		**34 meetings / 64 hours**			
Total hours on-line		**136**			

Table 1: Virtualizing course structure

The Virtualizing program began with the all participants taking the course "Virtual Learning Environments" - I (AVA - I), divided into their respective groups, ten hours per week for a period of 2 weeks (April 25th to May 10th, 2002). The objective of this course was to facilitate the digital immersion of all the participants into the program. The mainconcepts covered included basics of on-line learning, and how to operate and collaborate in the program's virtual environment (VIAS K). This was an important first step, since nearly all of the teachers in the program were novice computer users.

The authors, involved in the instructional design and systems design process of VIAS-K for the Laboratory of Distance Education, were responsible for designing a subsequent course AVA II for the Virtualizing program, highlighted in grey in table 1 (above), and discussed in detail to follow.

Course AVAII

The course Virtual Learning Environments II -AVA II, was specifically designed to extend the teachers' knowledge of virtual learning environments and digital resources in general, aiming to empower them with the knowledge and attitude necessary for managing classrooms in today's information society. The course was divided into 6 modules: Introduction; Components of Virtual Learning Environments; Educational Design for the Information Society; Strategies for Technology Use in the Classroom; Using the Web for Didactic Resources; Methodology for Constructing Virtual Learning Environments. The information in each module was offered in 3 distinct ways: 1. A descriptive hypermedia document, containing images exemplifying ideas and links to various related sites/documents; 2. A fictitious narrative about a grade school student's experiences interacting in a futuristic learning environment; 3. Tests for auto-evaluation, and instructions for relevant individual or group activities. Activities included contributing reflections on provided literature in an online discussion forum and chats, evaluating online educational material and creating an

BEST COPY AVAILABLE

annotated bibliography of internet sites relevant to each participant's subject area, creating a basic home page for the subject area (via online forms), and devising a strategy for a classroom activity which would use the internet.

The content was made available on the VIAS-K platform in a non-linear manner - each user could access any part of the modules in any order he/she wished. However, a suggested course chronogram was provided to guide users towards course completion. The course chronogram was designed so that topics covered in synchronous meetings (chats, videochats and face-to-face) coincided with AVA II course content and activities in a progressive way. Evaluation was informal (critical feedback without giving a grade), geared toward encouraging and helping participants to successfully complete the course activities. A motivational strategy was designed based on project exposure - each participant was expected to publish his/her site on the Virtualizing Program Portal, thereby making their findings available to local colleagues and teachers around the world.

Long-term Objective: Sustainability and Growth

The authors designed AVA II with long-term objectives in view. Each time the course AVA II is completed by a group, the number of teachers' sites published on the Portal will increase, annotated lists of internet resources will be updated and participants experiences documented, thereby creating a rich data base of useful and relevant information. These long-term objectives are designed to give a sense of continuity to the program, and are expected to be a motivational factor as the knowledge constructed by participants in the program is exposed and shared.

Final Considerations

The basic premise of the Virtualizing program is that the best way for teachers to upgrade their computer skills is through immersion in digital environments. For many participants of the program, logging on to the system and accessing course materials were major first steps. In the course AVA II, many of these novice internet users took seemingly giant leaps forward by conducting searches and evaluations of educational internet sites, and creating their own home pages and classroom strategies for internet use, something most of them couldn't conceptually imagine being able to do in the weeks preceding the course. The hands-on approach helped to demistify the media as well as give a sense of empowerment to the teachers. However, an indispensable element of the instructional design is the mixture of face-to-face and online activities and the support of tutors, to clarify difficulties and avoid feelings of isolation that can arise in pure distance education settings.

Technological Applications in a Graduate Special Education Program
Le Petite Technology

Maribeth Montgomery Kasik, Ph.D.
Governors State University
University Park, Illinois 60466, USA

Technology usage in higher education classrooms for service delivery has increased tremendously over the past 30 years. As an illustration of this point, this writer offers the following timeline as an example. As an undergraduate student in the late 60s and early 70s the only technology required of students was perhaps a calculator and typewriter. Professors lectured in large lecture halls with the use of chalkboards, overhead projectors, slide and movie projectors. This technology requirement for the "beginning teacher" was to be prepared via the "AV" da jour. Classroom teachers were equipped much the same way as the university professor. The public schools this writer experienced between 1970 and 1981 did not offer to their teachers or students computers for service delivery. There were initial computer hook ups at some schools in the city of Chicago that were linked to mainframe computers at the University of Illinois. However, these large computers were reserved for an elite few and not available to the general student and faculty populations.

As a student, the very first course in computer technology experienced was in 1969. The room was filled with keypunch machines and monitor-less keyboards "hooked up" to a main frame 200 miles away. There equipped with our plastic flow chart stencils, and computer paper, we learned the basics of "computer-speak" such as FORTRAN, COBOL, Pascal and of course BASIC. The fun everyone waited for was the opportunity to insert their cards into the key punch machine. The terror came waiting to see if those punched cards would actually run the program that we created.

At this very same time that the computer was emerging into the general population, the technological advances for the computer were being used in government agencies and some industries. As a college student in education, computers were not something essential if one was to be a teacher, let alone a teacher of students with special needs. Faculty really did not give computers any thought about being part of their daily existence. The next encounter and first university requirement to use computers in higher education for this writer came in 1977 as a graduate student where statistical research had to be entered into the computer mainframe using keyboards (this time connected to monochrome monitors) while sitting on a stool bolted to the floor in a large modern computer lab. After one's data was entered, one would wait at the job bin for their "job" to be processed.

Not until 1981 while a doctoral student at Southern Illinois University at Carbondale did PCs enter into this writer's daily reality. Statistical data was still entered into the university mainframe at this time; faculty did not have computers on their desks (nor did the staff). The IBM Selectric typewriter was the main technology for word processing. One day an Apple IIe computer showed up in the department office. It sat in a box for months because no one wanted to set it up or learn how to use it. With permission from the head of the department, this writer, on her way to becoming a certified "geek" set this computer up and running with little effort. Yet, it was not until 1984 that money was available to purchase her first Apple IIe computer for personal use.

Concurrently, this professor began teaching at Governors State University in Illinois where she re-designed a graduate program in Multicategorical Special Education. This program was to be a state of the art program for Master teachers to provide them with the skills that would make them and their students the most successful. As part of that curriculum, she developed a course: Educational Applications of Microcomputers in Special Education. The initial intent of this course was to help teachers see the need for computers; the uses for computers; learn of assistive technology and overcome any fears of computers.

Very rapidly through the 80's and 90's one could barely keep up with the almost daily advances with computers and technology. Computers began appearing in the public schools and university classrooms. There were personal decisions to be made about commodore, apple series and IBMs. As much as this user of technology loved the Apple series, in 1992, the IBM series leaped ahead. Presently used as a favorite is a Present Dell Laptop with 1 Gig Processor and 40 Gig Hard Drive 256 Meg RAM.

The early years of this course found the professor spending a great deal of time working on the elimination of basis techno-phobias among graduate students. Early lectures and class applications included learning Apple Basis, Logo, DOS, How to turn the computer on and off, Simple Assistive Devices, Computer Assisted Learning, How to Initialize a disk, etc. Students appeared excited in the university classroom about using the computer in their jobs, but found resistance came on the part of administrators and parents who felt that the computer was a toy such as Atari and just games like PacMan. Students could not learn if they were allowed to play games. Many graduates would report back that they were not able to use the school computer lab or that there wasn't time to use the computer sitting in the back of their classroom. For many years, this was the only exposure to technology that students in the graduate program would find.

During the 1990s the emergence of computer labs began to flourish and develop further. The computer was just beginning to be seen as something that could be used daily rather than once in a while by students and faculty. There were those that resisted even using telephones with voice mail systems at our institution. Many have memories of a professor stomping his telephone into pieces while proclaiming how he hated technology and would never use it. Even this professor had a change of heart when the day came that he could bring up his New York Times on the screen in his office.

Today we have technology standards, initiatives and guidelines. Students at several universities are required to have Personal Digital Assistants (PDA)s to bring to class with them. Some school districts are sending teachers to technology workshops to learn to use PDAs and other emerging technologies. Universities are finding it necessary to have "SMART" classrooms with projectors and internet connections and PCs for each student. Teachers and Professors have to be intelligent consumers of technology and the internet.

As of today, the use of technology has spread rapidly throughout the entire graduate program in special education. What began as just one course with technology has now grown to using the same applications in the majority of the classes. In 1984, 10% of the program was devoted to or delivered via technology. Today over 80% of the activities for the program require technology.

Hardware and software exist to deliver educational and vocational benefits to those with disabilities just as they exist for other people. Microcomputers as tools to which the effectiveness of depends upon the training and understanding of the use. with the changing educational environment as a result of the microcomputer, the special education uses of microcomputers have become endless as the technology, special educators need to be competent users of the resources available to them.

What follows are some of the slides that will be part of the PowerPoint presentation to accompany the text for this paper. The slides are illustrations from the current WebCt version of Educational Applications of Microcomputers in Special Education. WebCt is used by the professor as a supplement to the course. Included in the presentation are sample of student PowerPoint presentations and other technological applications.

Abstract: Knowledge management offers support in decisions making through the capture of the acquired knowledge in the organizational processes and on new technologies, the access to the domain of the business model, collaborative work and knowledge reviews among the employees. CardioResearch is a web-based tool that supports scientific research activities in an academic cardiology environment. CardioResearch can help physicians and cardiologists in decisions making during the execution of their tasks, and it can also help students gaining new insights while the organization preserves its intellectual capital. CardioResearch is part of a knowledge management environment, CardioKnowledge, configured and adapted according to *Fundação Bahiana de Cardiologia/Unit of Cardiology and Cardiovascular Surgery*'s goals and particularities.

1. Introduction

The ability to systematically capture and manage the intellectual capital of an organization regarding its employee's experience, understanding, know-how and skills is emerging as the central theme in business [1], [3]. In an academic environment, there are new scientific findings every day, which means that knowledge is being generated faster than ever before. Medical knowledge is estimated to increase fourfold during a professional lifetime, that means physicians cannot practice medicine without constantly updating their knowledge [3],[4].

According to [1] and [2], the *Fundação Bahiana de Cardiologia/Unit of Cardiology and Cardiovascular Surgery* can be considered, in cardiology domain, as an academic Research and Development (R&D) organization. Its focus is scientific research in cardiology and development of medical informatics software.

R&D, in *Fundação Bahiana de Cardiologia/ Unit of Cardiology and Cardiovascular Surgery* takes place in four different aspects: (i) participation in Clinical Trials; (ii) research in master and Phd thesis; (iii) research while providing medical assistance to patients in the ambulatories; and, (iv) research in medical software developing.

These four aspects require from the physicians skills in various areas, including application domain, computer science technologies and research methodologies [1].

Motivated by these aspects, CardioResearch has been implemented to support scientific research activities in an academic cardiology environment, helping physicians and cardiologists in decision making, helping students in generating new knowledge and the organization in the creation of innovative and creative solutions.

2. CardioResearch

Taking knowledge management as quality differential in the process of organizations with different business types, such as consultancy, medical assistance and research and software development, a knowledge management environment named CardioKnowledge has being configured and adapted according to *Fundação Bahiana de Cardiologia/ Unit of Cardiology and Cardiovascular Surgery*'s goals and particularities.

CardioKnowledge aims to support knowledge management's main functionalities[7]: (i) *knowledge identification*, identifies organization's goals in a way to be configured and adapted for it; (ii) *knowledge acquisition*, captures, in a structure way, organization's internal and external knowledge; (iii) *knowledge use*, uses the knowledge acquired in a way to support business organizational process; (iv) *knowledge creation*, creates new knowledge through use and reuse of existing knowledge; (v) *knowledge dissemination*, defines manners to deliver relevant knowledge in the right moment to the right person; (vi) *knowledge valuation*, utilizes metrics to evaluate knowledge; and (vii) *knowledge maintenance*, eliminates irrelevant and obsolete knowledge.

In this context, a web-based tool of the environment CardioKnowledge, named CardioResearch, has being developed to support knowledge creation functionality, as illustrated in Figure 1. This supports is given through knowledge use and reuse in a basic environment in terms of innovation and creativity.

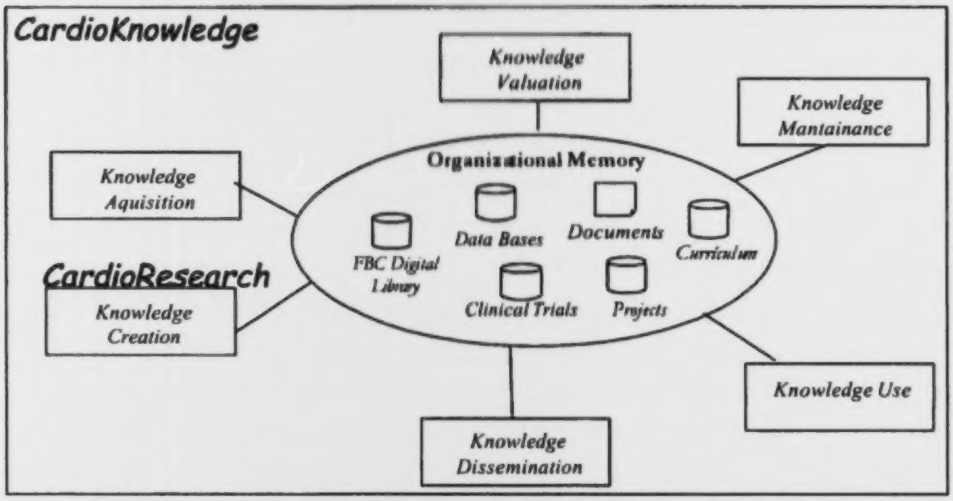

Figure 1: CardioResearch, a web-based tool to support knowledge creation functionality.

The *Fundação Bahiana de Cardiologia/ Unit of Cardiology and Cardiovascular Surgery* (*FBC/UCCV*) does four types of research: (i) participation in Clinical Trials; (ii) research in master and Phd thesis; (iii) research while providing medical assistance to patients at the ambulatories; and (iv) research in medical software developing.

CardioResearch can support the activities, at clinical trials participation and research in the ambulatories.

"Clinical Trials are a type of research study that tests how well new medical treatments or other interventions work in people. Such studies test new methods of screening, prevention, diagnosis, or treatment of a disease. The study may be carried out in a clinic or other medical facility." [8].

The ambulatories of *FBC/UCCV* have the following objectives: (i) provide cardiologic attendance to the patients; (ii) promote cardiology teaching to students of the Federal University of Medicine of Bahia and the residents of cardiology at *FBC/UCCV*; and (iii) to accomplish scientific researches.

The *FBC/UCCV* participates in several clinical trials studies and accomplishes a great amount of researches in the ambulatories, thus the research in a cardiology domain is knowledge intense process. Such knowledge, at *FBC/UCCV*, is easily lost, because it is not documented in its organizational memory; besides that, this knowledge is distributed in the employees and doctors' mind, hindering the accomplishment of the researches.

With the purpose to support cardiology researches in decision making while executing their tasks, the CardioResearch tool was proposed. It is integrated into the knowledge management environment CardioKnowledge, which seeks the explicit representation of the *FBC/UCCV*'s organizational memory, see Figure 1. CardioResearch can support the research activities in the following ways:

First, in order to form a qualified team to participate in clinical trials is necessary to combine physician's experiences to clinical trial's particularities. CardioResearch indicates qualified physicians combining key-words in their curriculum with clinical trial's characteristics filled out, previously, in forms. CardioResearch storages and retrievals documents in a document repository located in the organizational memory, in that way, clinical trial's results can be documented and shared allowing exploitation of experiences acquired from past trials and consequently avoiding repetition of mistakes. CardioResearch also provides tutorials to train the clinical trial time. This tutorial contains the workflow process of the clinical trial and varies according to its purpose.

Second, to start a research project through patient's assistance in ambulatories, research's requirements are identified, a team of physicians and medicine students are defined, and an infrastructure is prepared to support research in the project. In this context, CardioResearch offers a module to help physicians organize research's information (e.g. research's main goals, project team, results, etc) through hypermedia forms. All this information is stored in and can be retrieved from a project repository in the organizational memory. To help selecting qualified students to set a team, CardioResearch promotes calls for participation with forms that are filled by students and evaluated by the coordinating team. To train selected students CardioResearch provides manuals describing procedures that must be following facilitating knowledge reuse.

Third, CardioResearch also promotes a learning environment where the student can be involved in patient cardiologic care receiving specific training. At this moment education, takes place in two ways: in the ambulatory, physicians and students discuss and analyze patient's records in order to reach a conclusion of patient's therapeutic plan; and in clinical meetings, where students and cardiologists discuss critical analysis, statistical results of clinical cases and current cardiology issues, correlating them with ambulatory cases. CardioResearch also uses a personalized digital library [5], adapted to *FBC/UCCV*, named CardioLibraryFBC, with the purpose to capitalize knowledge gained by the students after finishing their degrees. This tool stores students' thesis and scientific papers facilitating organization's library collection management and literature's research and study. This helps students in gaining new insights performing and achieving the state of the art in their academic works.

Four, to prepare an infrastructure for research in patient's assistance ambulatory, medical software development is required. In order to provide that, a software engineering team develop medical databases used by CardioResearch to provide chart analysis to demonstrate research solutions and results in classes, conferences and meetings.

3. Ongoing Work

CardioResearch is still a work in process; the approach that is being used integrates knowledge management concepts and organizational processes.

The approach includes the following phases: (i) knowledge identification, in this phase requirements were identified building relevant knowledge; (ii) organizational process's identification and knowledge acquisition; (iii) process modeling through workflow; and, (iv) development of CardioResearch. The first and the second phase were completely finished and we are on the third phase validating the processes of *Fundação Bahiana de Cardiologia/Unit of Cardiology and Cardiovascular Surgery*, in meanwhile we are specifying CardioResearch's development.

Developing a WICeD® Team

Peter Moodie
WICeD®
The University of Waikato
New Zealand
p.moodie@waikato.ac.nz

Abstract: The University of Waikato has a very successful e-learning story to tell. This paper looks at how the Waikato Innovation Centre for e-Education (WICeD – pronounced 'wicked') team develops e-learning software and explains why it has been so successful since its formation. A research project highlighted some particular tools and techniques used daily in WICeD to focus development efforts on the teaching and learning rather than on the technology. This paper reflects on the use of those tools and makes suggestions for the formation and development of any e-learning development team as a result.

Introduction

This paper is not about e-learning tools, systems or even specifically about the pedagogy of e-learning. It examines the establishment of a successful and innovative e-learning development team in a university environment. By taking a close look at the development of one component of our e-learning environment we have discovered some important points about the way in which an e-learning development team can be constructed and can work together to produce very successful results. In this paper I will outline the processes which led to the creation of our e-learning programme and development team and will propose some key points to keep in mind for the development of any e-learning development team.

The University of Waikato has been formally involved in online teaching and learning since 1996 when we ran our first pilot online course. Before this the University had not been involved in teaching at a distance either online or via correspondence. I was involved in the establishment of the pilot and took on the role of the technical specialist. Following the success of the pilot, my involvement in the technical development of online learning grew until I became Learning Systems Manager at the beginning of 2000. I have taken and adapted this role to focus specifically on developing our online capabilities through the development of online communities. My role is now that of the E-Learning Systems Development Manager in the Waikato Innovation Centre for Electronic Education (WICeD).

Developing our roots in e-learning

Since the inception of e-learning at Waikato growth has been enormous. We have moved from providing one course fully online with 30 students to providing 130 courses fully online with over 800 students. In addition to this, we now also have over 700 campus based courses utilising e-learning technologies – catering to over 5000 students. The original focus of our e-learning activities was in the field of teacher education and has continued through to other disciplines that tend to be taught in a collaborative mode. It is this growth, along with both solicited and unsolicited feedback from learners and teachers, which has led us to believe that our e-learning programme has been a success.

The information and communication technology used by the University has matured over the period we have been learning to teach online. When we began online teaching we, like so many others, started by trying to teach using a software package designed for the "transmission" model (TopClass). It taught us a lot about teaching and learning in the e-learning mode. The key lessons were that learning always comes before technology, that the transmission model of teaching was no more effective in the online environment than face-to-face and that the strengths of our institution were in the field of collaborative and community based e-learning.

1988

In retrospect these conclusions seem fairly self evident. They will not come as a surprise to any experienced e-learning institution. However, the process by which we learned these facts was important for the formative years of WICeD and the development of its in-house e-learning tool ClassForum™.

By 1999, TopClass was proving to be inappropriate for supporting the collaborative style of online teaching and learning developed at Waikato. The search was on once again for a tool which would allow us to concentrate on teaching and learning activities – picking up particularly on the collaborative and community based approach to learning – without being forced into a rigid courseware framework. Several tools seemed to meet many of our needs, however, none of them was designed specifically as a Learning Management System (LMS). The final selection criteria, therefore, was the ability to programmatically adapt the tool and build in links to student administration, authentication and assessment systems.

ClassForum, conceived early in 1999 at Waikato, was born in late 1999 and is based on *Web Crossing 4.1* which is a powerful and fully customisable online community package. ClassForum, along with the underlying Web Crossing technology, has undergone a great deal of evolution and enhancement since we began. Development started with simple enhancements to assist in classroom management such as class lists and user interface changes. Then came the development of more sophisticated teaching and learning tools such as peer assessment modules and personalised workbooks. Development is now underway on the ClassForum Learning Object Library (LOL) which is a means of collecting and sharing innovations and teaching methods and tools within the ClassForum teaching community.

Also, during 1999 the University re-visited its strategic goals and as a result of the review listed "Leadership in E-Learning" as one of the "five key strategic objectives by which the University will achieve its vision and strategic intent"(Gould 2000). One of the main outcomes of this focus in strategic direction was the formation at the beginning of 2001 of the Waikato Innovation Centre for Electronic Education, which is referred to as WICeD. In the year leading up to the formation of WICeD the development and growth of the ClassForum system continued in the Campus Media unit of the ITS Division.

Reporting directly to the University Vice-Chancellor, WICeD is a team of 17 staff who are dedicated to furthering research and development in the field of e-learning. Many of the WICeD staff were recruited from the ITS division – including the Director, who gave up his long term role as Director of ITS to take on this new venture. The staff of WICeD include: four Learning Designers, three software developers, an e-learning systems manager, a video producer, audio developer, usability specialist, 3D modeller, two graphic artists and two administrative staff.

Designing a new e-learning support tool

In 2001 I completed a Postgraduate Certificate in Tertiary Teaching. This was to further my understanding of teaching and learning in Higher Education and because I recognised the need for ever improving approaches to development within my workplace environment. As a result, an assignment component of this qualification was a research project in which I examined techniques for developing elearning tools within a Higher Education organization. The title of which is *Focussing on Teaching and Learning in the Development of an E-learning Tool*. It examines the process of developing a new set of tools within ClassForum by the development and learning design team in WICeD. What follows comes from this research.

Initially, I assumed that I would be involved with, and reporting on, a fairly typical user centred software development process. The aim of the development was to design, program and implement a wizard based tool to enable teaching staff to create complex teacher-to-student and student-to-student group discussion systems within their online teaching space. The prototype system had been developed by myself in 2000 in conjunction with one teaching staff member who had requested a tool to create private teacher-to-student 'Portfolios' which allowed for a space in the asynchronous discussion tool shared only between the individual student and their teachers.

Now that WICeD was established and there was a very skilled team of professionals available to work on the enhanced project I expected a larger, more robust and flexible Portfolio type system to be developed. This new system was to be known as the Electronic Workbooks System (EWS). In the process of developing the EWS I made a number of interesting discoveries.

The first key educational issue was determining the extent to which teachers should be involved in the development plan. Would using a team of teachers on this development project lead to an outcome suited to the needs of the majority of eventual users? My initial thoughts on this were that it had to be an improvement over having the opinion of just one user participant in the design process, as had happened with the prototype tool. However, the difficulties of such an approach seemed equally obvious based on our experience in several previous design and development projects. The process of forming a user (teacher) consulting group would immediately present two problems which could compound the initial problem. The group would be self-selecting. Teachers who volunteered would very likely do so for one, or both, of the following reasons. There is a high likelihood that they would be keen users of the software and early adopters of new technology into their teaching practice. Secondly, those who took the time to be involved would be more likely to have their own specific needs in mind and, therefore, may approach the task with a narrow focus while WICeD enjoys the luxury of having an overview for the whole University.

In the case of those who were typically early adopters of new teaching technology, the feedback may not clearly reflect the needs and approaches to using software that a 'typical' teacher might have. Their prior experience, and often even enjoyment of using new tools, where they had to explore and learn from mistakes, could cloud their judgement in favour of a system more complicated than is ideal. For those with their own specific needs in mind, many aspects of a tool's use might be ignored in favour of the specific need they identified. The final problem was, of course, the fact that time considerations during the development 'window' meant that there was a high likelihood of not being able to get enough time from any teaching staff. This debate regarding representation is central to questions about finding the balance between technology and educational needs.

It was this difficulty, and the approaches we took to alleviate it, which led to the discoveries we made and to clarifying why our approach to the development of e-learning tools has been so successful.

Using WICeD expertise in the design process

Early in the design phase of the EWS project the decision was made by the development team to include a wide group of teachers later in the development process than we would normally feel comfortable doing. This was as a result of the difficulties in finding that elusive character, the perfectly representative teacher. The plan was to design and develop a working version of the tool using our own ideas and knowledge of the problem teachers were trying to solve – then test our understanding against a group of teachers in a formal usability study.

Given the risk of failure this posed, we had to use some techniques to attempt to maintain our user and pedagogical focus throughout the design and development process. Two techniques, role playing and conversation, were used to try and do this.

The first technique was to use role play during the design and development phases of the project. This was part of the action research approach I had adopted. My official role in the development team was 'architect and project manager'. Another member of the team was one of our learning designers and his role in the development process was to maintain focus on the pedagogical aspects of the development. Aside from our formal roles in the project, we both agreed at the outset to deliberately role-play as teachers who would use the software throughout the development process. During the project development cycle we did not mention this decision to the other members of the team.

Secondly the meetings throughout the project were conversations held between colleagues with a common goal in mind rather than formal agenda based meetings. Clark (2001) says of a good conversation; "Good conversations demand good content … good conversation resists the bounds of definition … is voluntary … happens on common ground … requires safety, trust and care … good conversation develops" and "good conversation has a future". The meetings held during the development of the new Portfolios tool displayed all these general characteristics of good conversation.

Using conversation in the development process was not a new phenomenon for WICeD, but evaluation of transcripts of these conversations did demonstrate that the conversation style of meeting allowed for more 'thinking aloud' which led to many holes in the product being plugged before implementation. The combination of role-playing and using conversations led to a very good representation of the characteristics of the general user community.

User feedback after four months in operation has been consistently positive. Requests for enhancements and additions to the EWS system are now he norm rather than requests for assistance in creating workbook equivalents. Faculty have gone on to use the EWS in ways that even the original design and development team had not imagined. This has demonstrated to us that the flexibility and robustness of the tool which was enabled through the thinking aloud and role playing techniques has been effective.

Conclusions

Evaluation of the development process for the EWS led to a very important discovery about how the way WICeD was formed, and the way it works is applicable to other e-learning development teams. The WICeD team was established as a result of the organization recognising the need at a strategic level for central funding to establish the development of an e-learning innovation centre. Of the 17 staff who currently work in WICeD, eleven have had some, or in many cases, considerable teaching experience in the Higher Education sector. Those members of the development team consistently approach their work with teaching and learning foremost in their minds. For a technology development unit this is exceptional – for an e-learning technology development unit perhaps it should be the norm.

Without keeping teaching and learning at the forefront of e-learning developments, the results will continually drift towards technologically 'tidy', but pedagogically lax results. The supportive and proactive climate at the University of Waikato, which led to the formation of the WICeD team from a group of pedagogy aware technologists and technically aware teachers, has proven to be a successful model for the formation of an e-learning development team. Innovative approaches to teaching and learning are set to continue at a pace in WICeD.

Increasing Teacher Certification through a Multi-Campus (Blackboard) Praxis Network

William E. Moore, Willa M. Moore, Ann W. Henderson and Mous Diack
Colleges of Education and Sciences
Southern University
Baton Rouge, Louisiana 70813 USA
billsubr@aol.com

Abstract: In this paper we describe the development and implementation of a test preparation network for students enrolled at four universities in the state of Louisiana. The network uses the course management software *Blackboard* as a medium for test preparation, posting resources, and conducting collaborative projects among universities. The network has a strong accountability component and provides for good statistical tracking of student activities. One noteworthy and unique feature of this project is that the network enables students from four universities to benefit from the general strengths and faculty expertise from four institutions. We will illustrate several of the local instruction models we have developed and indicate how the methods may be implemented on a larger scale.

Introduction

The popularity of e-learning is evidenced by the unusual proliferation of online courses and degree programs. Despite this unprecedented growth, controversy prevails regarding the effectiveness of this mode of instruction (Chamberlin 2001). Two years before this date, we had begun to capitalize on a middle-ground approach that combined face-to-face instruction and online learning. We then extended this methodology to include a network of four universities (The J. K. Haynes Consortium) addressing the common problem of preparing students to pass threshold examinations for teacher certification. Initially activities were confined to individual campuses and we reported our findings in annual faculty development and planning conferences. The participating institutions included Grambling State University and Southern University Campuses at Baton Rouge, New Orleans and Shreveport.

In the summer of 2001 we discovered that our consortium of schools possessed an ideal infrastructure for establishing a web-based network. For example, it could provide learning resources for students, serve as a medium for faculty development and program planning, and provide opportunities for collaborative learning among campuses. Equally as important, the network would allow the consortium to fill gaps in knowledge so that we could witness higher passage rates on the Praxis examination. To this end, we elected to use the course management software system, Blackboard, as the central tool for implementing the network. The uniqueness of this collaborative network is that students from four campuses benefit from the faculty expertise from these universities and that it provides a medium for the rich exchange of ideas among students and between students and faculty. The archives also provide valuable documentation and elements of accountability. In this paper we describe model activities that were carried out on the Baton Rouge campus of Southern University.

The Study

In our local model, we chose to employ the middle-ground approach involving students from four different classes. This arrangement included two sequential six-week Saturday workshops with an average of 47 students per six-week session. This program was part of the J. K. Haynes outreach initiative and the sessions involved regular university students and some commuters who traveled as much as 130 miles to receive face-to-face instruction. The second component involved two eight-week reading classes that were offered concurrently in the summer of 2002. One class was devoted to teaching reading for elementary school and the other reading class focused on teaching reading at the secondary level. A third component of the local network involved a *Blackboard* faculty development thrust designed to create a Praxis-based e-learning culture. For clarity, these initiatives will be discussed separately.

The Saturday Outreach Workshops

The class associated with this activity met four hours each Saturday (9:00 a. m. to 1:00 p. m.) for six successive weeks. During this time period, four faculty members offered instruction around the various components of the Praxis II examination. The first week was devoted to administering a diagnostic test and familiarizing the students with features of Blackboard. The former enabled faculty to determine student deficiencies requiring intensive work or individual attention. The latter was designed to enable students to begin using Blackboard immediately. For this purpose, we created a test bank of approximately 860 discrete multiple choice test items. By the end of the first week, students could access the available test items at their convenience. The faculty could monitor student progress and use the information to determine appropriate types of intervention. When we analyzed the Blackboard statistics, we began to see a strong correlation between usage and performance on the actual Praxis Examination. A student who had average scores on 12 of 15 Blackboard exams showed a greater likelihood to pass Praxis than one who had high scores, but only took three of fifteen exams during the same time period. In short, the intensive Praxis based instruction the students received on Saturdays proved to be an appropriate complement to Blackboard usage during weekdays.

The Summer Reading Classes

In the summer of 2002, .approximately 29 students were enrolled in each of the two reading classes for education majors to learn methodologies for teaching reading at the elementary and secondary levels. For the purpose of Blackboard activities, the classes were placed in the same Blackboard classroom. However, they were not physically combined and students never met one another except through a non-class coincidence. In this way, the students were able to take advantage of available test items and which gave the faculty the opportunity to experiment with collaborative learning across the physical boundaries of brick and mortar classes.

In the collaborative learning project, students were divided into groups of six each, with three students coming from each of the reading classes. Each group was given a name (Piaget, Bloom, Montessori, Locke, etc) and placed in the Discussion component of Blackboard. Access was restricted to members of a given group.

The entire *Blackboard* class was given 15 analytical reasoning problems and instructed to solve them collaboratively. They were informed that each student was required to provide leadership in discussing three problems and was required to participate in the discussion of all problems. They were given a deadline of midnight July 23, 2002, to complete the problems and submit a consensus report .In this section student interaction was high but some did not complete the consensus reports. More than 70% of the students indicated that they benefited from the asynchronous cross-fertilization. In an earlier study we had conducted in a similar class, the consensus reports were much higher -- largely because we had grade bonus points attached to acceptable completion of the reports.

Students in the reading classes were also required to develop home pages and place Praxis relevant material at these respective sites. These included case histories and other activities involving reading and writing skills. We found that some students had significant gaps in knowledge regarding human development, assessment and education in the courts. To this end, we created Power Point review activities and placed them in the course document section of Blackboard..

An important aspect of the reading activities was that seven faculty members were placed in this combined class as observers who could also engage in exchanges with students and offer them advice or cues to their respective problem. This part of the model is a scaled down representation of what would happen at four universities across the state of Louisiana. In this case we envision a group of students from four universities working on an assignment and having faculty members from these universities provide clues, mentoring support and insight through the Blackboard discussion forum. The preliminary results we have received suggest that there is vast potential in this application (Horton 2000).

Discussion

The results we have obtained from the four classes we have studied locally suggest that Blackboard can serve an important role for creating a culture that will accommodate e-learning and teacher certification. The creation and use of the 800-plus item test bank provides evidence of its utility. We have also demonstrated that asynchronous, peer-based collaborative learning is an important tool for filling gaps in knowledge. We further show that there is a strong positive correlation between frequency of Blackboard usage and performance on the actual Praxis examination. We are equally convinced that web-based faculty development is workable and that it provides a powerful means of exchanging ideas and teacher certification resources.

The next step in the Praxis preparation process is to implement the multi-campus network. This will include faculty development, local face-to-face instruction and a robust combined Praxis virtual classroom for students of the four campuses. We will track course statistics and provide rigorous evidence of the effectiveness of the various components of this classroom.

KAKUSHO Koh MINOH Michihiko
Academic Center for Computing and Media Studies, Kyoto University, JAPAN

Abstract: In this article, we report our analysis about relation between the content of lecture and the students' eye movement in order to clarify the criterion to capture image information for distance learning. We classified content of lecture into nine instructional process categories: introduction, presentation, explanation, illustration, assertion, query, reply, question, and response. As the result of analysis, we get the characteristic of students' eye movement in each instructional process category in practical lecture. And our research suggests the practical guide for selecting of image information for distance learning

1. Introduction

The rapid advancement of the Information Technology (IT) such as the Internet has been changing education, particularly distance learning. In the case of distance learning, lecture with multimedia material is shot by some cameras, and the image information is recorded and transmitted. It is necessary to convey the content of lecture effectively, so we need the criterion to decide what we should capture by camera.

In the previous work, they proposed some automatic shooting systems and archive systems for lecture (Kameda et al.,2000, Onishi et al., 2000). These works were interesting in the visual point of view. But, we propose that it is important to consider contents of lecture for selecting of image information. Since students depend on contents of lecture in order to decide what they look at, we pay attention to students' eye movement.

Our purpose is to clarify the criterion to select image information for distance learning and WBT. Then, we report our analysis of how the students' eye movement is affected by the content of lecture.

2. Instructional process category

Lecture with multimedia material consists of lecturer, material and students. Multimedia material continues to be shown during the lecture. Students choose an object (material, lecturer and the other students) at which they look to get information. We define the style of this lecture as "multimedia lecture". In this multimedia lecture, the roles of lecturer and material change according to the situation. In this research, we examine the roles of lecture and material which affect students' eye movement.

A criterion is necessary to partition the multimedia lecture into parts based on contents. Then, we define "Instructional Process Category" referring to the past research of instructional analysis (Flanders, 1970, Hough et al., 1970, Mizokami et al., 1998) and teaching method. We classified contents of lecture into nine categories: introduction, presentation, explanation, illustration, assertion, query, reply, question, and response.

Introduction: Lecturer tells students about the preliminary knowledge and the outline of lecture so that he/she expects students to be motivated the lecture. In this process, lecturer gives students advanced organizer. We define this part as "introduction".

Presentation and explanation: We propose that the process of learning multimedia material classifies into two parts, referring to process of learning text (Kintsch, 1994). First, they learn of multimedia material. They try to recognize and understand the multimedia material in order to construct text-based model to replay and summarize the contents. We define this part as "presentation". Next, they learn from multimedia material. They try to integrate information and knowledge in order to construct situation model to apply the integrated knowledge. We define this part as "explanation".

Illustration: Lecturer shows a concrete example to help students understand. We define this part as " illustration".

Assertion: Lecturer asserts his/her argument and tells his/her experience. We define this part as " assertion".

Developing and Integrating Resources in a Virtual Learning Environment

Raul Morales and Yoneo Yano
Information Science and Intelligent Systems Department
Tokushima University
2 – 1 Minami Josanjima-Cho, Tokushima 770, Japan
{raulms, yano}@is.tokushima-u.ac.jp

Abstract: This paper presents an approach to develop and to integrate highly diverse resources in learning spaces via personalizable interfaces and virtual collaboration areas. Digital libraries comprise vast digital repositories and wide range of services, users' environments and interfaces, all intended to support learning and collaborative research activities. We are developing a distributed learning environments for which services and interfaces include, for example, web-based learning systems using annotation environment, adaptive WBL, agents-based asynchronous virtual classrooms, computer assisted language learning using video and annotation, teacher support environment in web-based training system, videoconference-based CSCL environments, user agents for video information retrieval and access to digital documents that support specific courses and projects. In order to assist users in dealing with this complexity, we are designing environments, termed collaborative personal and group spaces, which provide users with means to access and control all available resources in a uniform fashion from a single vantage point.

1. Introduction

This paper analyzes some of the majors problems faced by users when using collections and services provided by network learning environments or digital libraries and presents an approach for the integration of learning environments resources which is based on the concepts of personal and collaborative learning spaces. We posit that users should have at their disposal means to create virtual areas within the learning environment in which they can place information objects that are relevant to their interest and ongoing tasks. We refer to this sort of virtual space as a collaborative personal space (CPS). Additionally, digital libraries and learning environments should also provide users that usually work remotely with virtual spaces where they can meet to discuss objects and topics of interest and to work collaboratively on group projects while maintaining the capability to access materials in digital collections. We refer to this second category of virtual place as a collaborative group space (CGS).

Our group has been conducting research in the areas of computer supported collaborative learning (CSCL) and digital libraries (DL) and has produced advances both in the construction of digital contents and in the provision of e-learning for users in the context of distributed system architecture. In this context, we are designing and implementing one version of collaborative personal spaces and other of collaborative group spaces. We report our design and development experiences in this particular area of our learning environment.

2. Environment Context

One part of our group has been working in a system architecture for a learning environment in a Digital Library that addresses the needs for information management, communication and collaboration among a highly distributed community of users. We have aimed to build both a practical, functional learning environments and a

BEST COPY AVAILABLE

testbed for research of open issues in the field, including aspects of personalized and groups interfaces, collaborative work and information visualization.

The realization of our learning environment has called for research and developed efforts in three major areas: building content, designing components that provide general infrastructure such as information retrieval services, multimedia management and agent essentials, and user interfaces and environments. Our advances in the area of general infrastructure include a distributed framework that integrates services and interfaces, with implementations using KQML, servlets and RMI as well as components implementing various popular information retrieval mechanisms. Finally, in the area of user interfaces and collaboration environments, our work has resulted in various access and visualization mechanisms.

One distinctive element of our work in leaning environments is our view of information and collaboration spaces as comprising both the digital and physical realms. We believe the needs posed by learning activities can be satisfied if traditional resources as well as the novel digital facilities are accessible to users at any given time in a seamless fashion. In this regard, we have been integrating traditional on-line learning material and user services in to our new developments. As can be expected, software components such as CoCoA, AVC, Sharlok and LeComm consider that both digital and physical resources should be accessible to users.

Even though each software component may facilitate seamless access to some learning resources, the diversity of such components as well as the size and dynamic nature of digital collections and user communities have the potential to make the digital library a complex and unwieldy environments for end users. Means are needed to ensure that individual users have access to exactly the resources they are entitled to according to their roles, needs and preferences. Providing more that a user needs unnecessarily increases the system's complexity and the user's cognitive overload. On the other hand, limiting access excessively would result in system under-utilization and user frustration. The needed compromise should be the result of electing and addressing every user's needs and preferences. Learning environments users typically need to work collaboratively as in a school or in a physical library. More often than not, a given user belongs to more than one regular group of users. It is also possible that learning or library resources are disjoint for every group a user belongs to, or that some materials need to be used in several work groups. Thus, for example, a user may participate in a class discussion for which he is the instructor or facilitator and also in a technical committee that is reviewing a paper submitted to a conference. For him class, he may suggest a reading (available at the digital library) which happens to be, say, a missing reference in the paper being reviewed by the other group in which he participates.

The work described in this paper aims to advance along these lines: facilitating the creation and maintenance of personalized areas (which we call collaborative virtual spaces) that integrate resources relevant for a given user , and making possible for users to easily move from personal to group areas sharing digital content in an adaptive video-CSCL environment.

3. Collaborative Virtual Spaces

In the context of a learning environment, we define collaborative personal space as a virtual area that is generated, owned and maintained by a user to persistently keep resources like objects, agents, etc. or references to resources which are relevant to a task or set of tasks the user needs to perform in the learning environment. Collaborative personal spaces may thus contain digital documents in multiple media, personal schedules, visualization tools, and user agents. Resources within collaborative personal spaces can be pre-assigned according to the user's role. For example, a research student would have access to research-specific topic materials, visualization tools and interfaces to communicate (video, audio or text based chat) with his colleagues. Agents may be available for recommending research or library materials that are relevant to the research topic and the collaborative personal space could be enriched by the agent's suggestions.

Similarly, we define a collaborative group space as a virtual area in which learning environment users can meet to conduct collaborative activities synchronously or asynchronously. Explicit collaborative group spaces are created dynamically by a group leader or facilitator who becomes the owner of the space and defines who the participants will be. Implicit collaborative group spaces can be generated automatically when a number of users have been detected to have similar user profiles or interests around a given topic or task. In addition to direct user-to-users video-communication, users should be able to access research and learning materials and make annotations on them for every other group participants to see.

4. Implementation

We are developing prototypical implementations of collaborative personal and group spaces concepts in order to provide a homogenous interface to the various user services and environments described in last section. We based our designs on the well-known room metaphor [Greenberg and Roseman 1998; Henderson et al. 1986]. Collaborative personal spaces are thus conceived as rooms that every user may configure and adapt by defining some characteristics as color, furniture, layouts and by adding learning resources that are used frequently or support user tasks. We also have emphasized the role of every user in our prototypical interface design [Shineiderman and Plaisant 1994]. When users register to access the learning environment, they specify the role(s) the will be playing in the system. Typically, a user selects or is assigned a combination of the various existing roles; research, graduate or undergraduate student, full time or part-time professor, research staff, or system administrator. The initial collaborative room configuration is determined by the user's role.

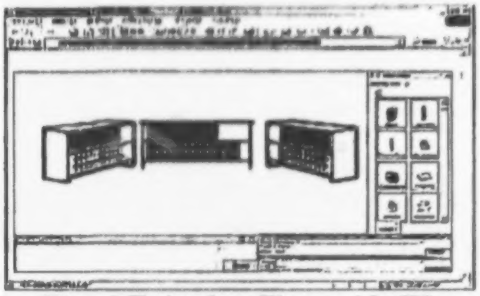

Figure 1. The interface of Hyzone – 1 for CPS.

Our first CPS prototypical implementation, which we termed Hyzone-1, is being developed to users in Java applets that could be downloaded and run at the client level. Figure 1 illustrates the interface of Hyzone - 1. The idea is straightforward: Users may configure their collaborative personal space by changing a room's physical characteristics and placing sheets icons (representing learning resources) into bookshelves that can be added and moved around at will. Drag-and-drop functionality can be applied practically to any element in the prototypical interface. The figure also shows icons for search tools and recommender agents. Menus include options for adding and removing elements from a room, associating learning resources with icons, sending instant messages to active users (same interest) and new elements can be shared by clicking pull-down menu.

Our current version of Hyzone – 1 implements explicit collaborative group spaces (as per our definition in the previous section): any user of the learning environment may create a CGS and send invitations to users who are members of a team or who are potentially interested in a particular discussion subject.

Figure 2 illustrates a session of five users who have started a discussion in Hyzone -1. Upon entering the "room" representing the CGS, every user sees a picture or video of himself, images or videos of the other users currently logged in, as well as icons that represent learning environment, which have been brought to the room to support the discussion. Users participate in the discussion by posting their comments via text interface and pointing to learning resources. Users can make annotations on shared materials (images and videos) and see other users' annotations. The entire discussion can be saved so latecomers may join a meeting and get up to speed quickly, or the discussion may be suspended and retaken by the group at different time.

In Hyzone -1, users can drag their own image or video and drop them near another user, group of users or learning resources. This is intended to reflect natural positions in a discussion in a visual fashion that can be perceived by all group participants. Alternative, new rooms or sessions may be created to include different sets

BEST COPY AVAILABLE

of users for addressing sub-topics or new discussion topics.

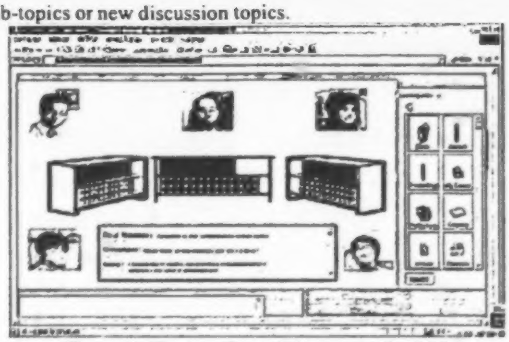

Figure 2. The interface of Hyzone – I for CGS.

Our ongoing-work implementations of collaborative personal and group spaces have undergone various usability and performance test with encouraging results. We have focused initial tests to our main target communities: college students, professors and research staff. For our tests we have used small collection of digital videos, articles, technical information and online information.

In addition to usability inspections test, we have been observing users experiment with the prototypes. With only minimal initial guidance, users of Hyzone – I have been able to personalize their information space by creating rooms, changing their appearance, and more importantly, by gathering learning materials and references (online entries) and placing them in bookshelves. From their collaborative personal space, users also have been able to open digital documents and launching applications such instant messaging and videoconference tools. However, some of the services and applications described in this paper have become available more recently.

From our results thus far, we believe collaborative personal and groups spaces are a promising approach to the integration of highly distributed, heterogeneous information spaces. Our design and prototypical implementations shows that our approach may effectively help users in coping with the size, complexity and dynamism of digital learning content.

The Use of Virtual Learning Environments in UK Higher Education - Are VLEs Supporting Student-Centred Learning?

Sue Morón-García
Institute of Educational Technology, The Open University, United Kingdom
s.d.moron-garcia@open.ac.uk

Abstract: This paper reports on doctoral work in progress investigating whether Virtual Learning Environments (VLEs) are being used to support student-centred learning in UK Higher Education (HE). VLE is the term used to describe the package of integrated software tools that make use of Web or Internet-based technologies and are used to put courses online. The focus of the research is the lecturer (HE teacher), because it is they who set up the learning environment for the student. The findings of a pilot study into the use of Web and Internet-based technology to support learning in HE were used to develop a main study which concentrates on the use of VLEs by humanities and social science lecturers in face-to-face education.

Introduction

This research investigates whether lecturers are moving towards a more student-centred model of teaching, facilitated by the use of Virtual Learning Environments (VLEs). The aim is to identify factors relating to the VLE, the context in which it is used and a lecturer's pedagogic model that may support or prevent this happening. The research questions are:

- Can Virtual Learning Environments support student-centred learning and how does the functionality of the system affect lecturers?
- What are motivating factors for lecturer use of Virtual Learning Environments and what prevents them being used?
- How are lecturers using them, what methods are they using, and how does this fit into their overall pedagogy?

The focus of this research is the lecturer (HE teacher), because it is they who set up the learning environment for the student. The findings of a pilot study into the use of Web and Internet-based technology to support learning in Higher Education (HE) were used to develop interview questions for a main study concentrating on the use of VLEs by humanities and social science lecturers to support face-to-face education. The main study also used the Approaches to Teaching Inventory (ATI – Prosser and Trigwell, 1999) to help identify a lecturer's pedagogic model.

Virtual Learning Environments

The most recent manifestation of Web and Internet-based technology packaged for educational use and promoted as a way for universities to get their lecturers online is the Virtual Learning Environment (VLE). The two most commonly used VLEs in the UK currently are WebCT and Blackboard. Some VLEs are based on specific pedagogic models, for example COSE (Stiles 2000), emphasising the use of communication and collaboration tools. The aim is to encourage a different model of teaching and a move away from the uploading of large amounts of content (the first stage of use for many lecturers) and the replication of what can already be achieved through print. According to a recent report the institutional motivation for the adoption of VLEs ranges from increased efficiency to the enhancement of teaching and learning, greater flexibility and a move towards distance education (Jenkins *et al*, 2001).

The Benefits of Using Web and Internet-Based Technology

Much of the writing and research relating to the use of Web and Internet-based technology deals with the perceived benefits for the learner. Those highlighted include the enhancement of study skills and the ability to participate in subject activities (Martin and Fayter, 1997) as well as the creation of transferable skills (Harrison, 1994). It is claimed that the new collaborative tools and new media actually afford a better learning experience for students (Gibbs, 1999), aiding understanding (Pimentel, 1999) and facilitating the sharing of knowledge (Harasim, 1989). It is claimed that the use of Web or Internet-based technology can facilitate the creation of a student-centred learning environment (Collis, 1996) and the adoption of a student-centred method of teaching (Westera, 1999). Student-centred approaches are advocated as a way of equipping students with the skills they need to survive in today's complex world.

Factors Affecting a Student-Centred Approach to Teaching

It is widely argued that student-centred teaching approaches encourage students to adopt higher quality approaches to learning - what Biggs and Moore (1993) among others call a deep approach to learning - and aid the development of critical abilities. It is argued that student-centred learning and learning environments designed with reference to constructivist theories of learning will produce in students the critical and cognitive skills that Higher Education aims to develop (CNAA, 1990, Jonassen *et al*, 1993, Thorpe, 2000). However, there may be pressures on lecturers to use particular approaches in their teaching. Trigwell and Prosser (1997) found that lecturers who felt that they had more control over their teaching (what is taught and how) were more likely to adopt student-focused approaches. These approaches were affected detrimentally if the class size was thought to be too large, student diversity too great and workload too heavy.

Elements in the institutional environment may affect lecturer usage of the Web and Internet-based technology such as access to equipment, training and support. Barnard writes about an obstacle course of barriers that have to be overcome if teachers are to move "from being non-users of technology to being fluent users who could integrate technology into their teaching" (1999, pg. 352). These include anxiety, unfamiliarity with the technology, resourcing, perceived usefulness, personal philosophy, the influence of colleagues and classroom dynamics.

Lecturers' beliefs about teaching and learning and how to create the most effective learning environments are fundamental to improving student learning. Previous research has shown that lecturers' conceptions of teaching correlate with teaching approaches that in turn correlate with student learning approaches and learning outcomes (Kember, 1997 for an overview). Trigwell *et. al.* (1999) built on previous research to show that lecturers' teaching methods correlate with the approaches to learning of their students and that student-centred methods are linked to deep learning approaches in students that in turn are linked to better learning outcomes

The Pilot Study

The pilot study was conducted in order to find out what was actually happening in Higher Education (as distinct from what the literature indicates may be happening):

- Were lecturers using Web and Internet-based technology?
- What sort of technology and how?
- Was pedagogy influencing the use of the technology?
- Were lecturers aware of their pedagogy?

The objective was to develop a series of interview questions that would facilitate the collection of data to answer the research questions.

Twelve lecturers from four universities were interviewed about their teaching and their use of Web and Internet-based technology, including VLE use. Consideration was given to the possibility that some lecturers may be more comfortable with the use of Web and Internet-based technology and that some lecturers may be more able to explain and justify their pedagogy. For this reason education lecturers and those teaching computer science were interviewed. A third category of lecturer, social science or humanities, with no obvious reason to feel comfortable with the technology or a reason to be familiar with pedagogic terms was also interviewed.

Findings

- The use of VLEs is not widespread, even within those universities that support use. The newer universities were more likely to have an institutionally supported VLE and have an institutional policy that encourages use.
- Use is restricted by access issues, student and lecturer IT literacy, student expectations and colleague use, time available to create resources and to become familiar with technology.
- The 'electronic filing cabinet' was thought to be valuable – it was convenient for both students and lecturers.
- The use of e-mail as a means of communication was becoming the norm, discussion forums were used with varying degrees of success, but there was some resistance from students and lecturers were unsure how to make best use of it; 'chat' was only used by one lecturer.
- Technology was used to support group work, reflection, contact with the lecturer, sharing of work, engagement with materials and content outside class time.
- Teaching methods adopted by lecturers were dependent on class size and influenced by the way in which they were taught, observing others and any training they had received, but the same method (for example, a lecture) meant different things to different lecturers.

Developing questions for the main study

There were discipline differences in the way Web and Internet-based technology was used that made comparison difficult, therefore it was decided to focus on the social science and humanities discipline areas where it was hoped there might be more of a pedagogic pull than a technology push.

It had proved difficult to identify a lecturers' teaching model, the same method, for example a lecture, could mean different things to different people and talk about VLE use had often been mixed up with talk about general teaching. Research relating to teachers' and lecturers' conceptions of teaching indicates that there is a disjunction between lecturers' conceptions of teaching and their claimed educational practice; so even if lecturers say that they are using student-centred methods they may not be in practice. Prosser and Trigwell (1999) developed the Approaches to Teaching Inventory (ATI) to overcome this disjunction and aid in identifying the intended and actual strategies used by lecturers. It was decided to use the ATI as one of the instruments for the main study. Lecturers were asked to focus on a specific example of VLE use when completing the ATI and to talk about the way in which the VLE supported and facilitated the teaching methods used in that context.

Questions in relation to a lecturer's level of IT literacy had not worked well, personally defined levels of expertise are highly subjective and mean little in comparison to other's self-claimed levels. It was decided to ask lecturers to define (and give examples of) their own comfort level with software applications and tools relevant to VLE use, for example a word processing package, a presentation package, Web authoring software and computer mediated communication tools. The data had also indicated that there were a number of other factors that influenced the use of a VLE such as the types of students being asked to use the VLE and the ethos of the department and institution in which the lecturer works.

Thirty-two lecturers across ten universities were individually interviewed about their use of their university's VLE (three of these were trial interviews, as part of the process of developing the interview instrument). The interview data is currently being analysed.

E-Learning & the Global Interface

This short paper begins with effective communications principles in contemporary multicultural and multinational classrooms and differing national and personal styles of discourse, and proposes their broader application to e-learning environments.

It examines several instances of their embodiment in sound screen and website interface design principles.

The paper closes on some design issues for new technologies (beyond the desktop Web browser) that will impact learning, stimulated by the author's Summer 2002 semester as an exchange professor in Japan.

Michael R. (Mike) Mosher has been an interface, Web and instructional animation designer for Apple Computer, IBM Almaden Research Center and Cisco Systems. He is now Assistant Professor of Art/Communication Multimedia at Saginaw Valley State University. Mike is the author (with R. Shepherd) of Creating Web Graphics, Audio and Video, Prentice-Hall Publishers, 2002.

Collaboration as a Response To Individualism

Robert Muffoletto, Ph.D.
College of Education
Department of Curriculum and Instruction
Appalachian State University
Boone, North Carolina

Abstract: This paper addresses issues related to the conception of collaborative learning as a design form for the Internet environment. Collaborative learning is positioned in opposition to the liberal/modern notion of the individual. In other words, how we construct the individual within a collaborative learning environment counters how western industrial society's attempt to construct the notion of the individual as a free agent responsible for their own success or failure. This paradigm counters how we think of students within a traditional learning environment-- one based upon merit and the business model.

Introduction

The Internet and related technological developments have allowed educators and students alike the opportunity to consider alternative forms of educational environments ranging from traditional instruction centered environments to community-learner centered learning environments. This paper will begin to outline a context for issues related to ideas concerning the individual in light of these movements. In doing so I am not taking a technological determinist perspective, but position technology as a systematic relationship to various processes and devices, woven together through ideologically based theories of application and practice, working within and through society.

There is no denying that developments in computer related technologies have effected how we think about education, leading to a paradigmatic shift framing teachers, students, and knowledge in a different manner. The Internet as a multi-mediated learning environment is providing "design forms" to educators through which to engage their students in the active pursuit of knowledge and application. The traditional classroom, the role of students and teachers, have been questioned and challenged as the result of the teaching and learning paradigm shift. It is now possible to create learning environments, over instructional environments that re-define the definition of teaching, learning, and the classroom. As we consider educational possibilities that include collaboration and cooperative models of interaction and learning, we need to re-think how the resulting learning environment constructs and re-constructs the idea of the individual within a perceived community of learners, over the autonomous individual within a crowd.

To consider the development and definition of collaborative learning environments we need to move beyond the "common sense" notion of technological and educational neutrality. We need, in a reflective manner, to contextualize the "idea" of collaborative learning communities within a historical and geographic construct. Not to do this will further lead to the mystification of process and the glamorization of technology as progress.

Why Talk About Collaboration

Talk concerning collaborative learning environments attempt to localize collaboration as a response to a history in the United States of "rational individualism" in education and educational technology. In other words, to consider learning environments based upon a notion of collaboration is in itself a direct response to the environment found in classrooms that is competitive, centering the curriculum within an instructional framework.

In thinking about a collaborative learning community, it is important that we see it in opposition to and different from, a non-collaborative environment centered on liberal individualism, progress, and technology. In education, liberal individualism is present in neo-behaviorist learning theory, which is centered on merit and individual measurable achievement. From this perspective, progress or learning in education is based upon presumed objective, measurable criteria, resulting from individual effort, and natural intelligence.

From this perspective, our educational system in the United States has been built upon an ideology of progress, science, and control. Education in the United States has been constructed on late 19th century and more developed 20th century models of management and control over labor and knowledge. In the modern world of the twentieth century we have witnessed how the individual was engineered by capitalism and a business ideology as an object to be controlled for the perceived good of a few over the needs of the many. In the post-modern world, where questions of identify and social justice drive much of the thinking, the individual is recognized as a member of a larger community bound together through history, language, culture, and geography. Post-modernism in education moves the discussion away from the individual as an object to be formed, to the individual as an emerging subject.

The construction of the individual from an object on the assembly line to the individual, as defined in an individualized, self-paced integrated learning system is a small step, but a major element in hegemony of the "ideology of the self" within a capitalistic, competitive merit based society. It is an ideology where the individual is held responsible for her or his development and progress. A progress defined by the system itself. This notion of progress is found in the current movement towards a standardized curriculum and high stake testing.

Contrasting the notion of the individual found in the community formed within the modern urban industrial society, to the concept of the individual as found in rural America, southern and eastern Europe, we see the individual woven into the fabric of the rural community. The individual in the rural agrarian community, gained her identity within the life of the community, and in return had responsibilities to that community. Whereas, the individual in the urban industrial community was defined by the system as an objectified object, a free agent, an independent contractor, who is responsible for his or her own condition and future. In one instance, the community engaged the individual within its own survival and definition, where in the other case, the individual existed in solitude in control of its own destiny.

If we reflect on the "idea" of the individual as an autonomous being, responsible for its own condition, it is radically different from understanding the individual as a member and defined by a community. In this case, the community shares responsibility for the individual, and the individual is responsible to the community. These forms of communities are held together through religion, family history, economic ties, and various practices. Communities of practice define their members, not as individuals, but as members. We can find examples of communities of practice in different locals. Individuals who share common labor practices, shared physical space, shared ideological perspectives, history of oppression, histories of wealth, team members, and class mates, all have borders (discourses) of different thickness and depth which unify them into communities.

In an educational system and its focus on the merits of the individual student, the individual teacher, and the individual school, the student, as well as the teacher, is constructed not as a member of a community of practice, but as an individual, who is judged by their behaviors in light of pre-determined outcomes and economic needs.

To speak of collaborative learning environments is to speak in opposition to the current dominant paradigm, which hosts individualism, competition, and an objectified measurable knowledge base. To speak of collaborative and cooperative learning environments is to embrace notions of democracy, community, shared responsibilities, and diversity. To speak of collaborative learning environments in traditional face to face classrooms, or in geographically dispersed ones, moves education away from an historically grounded, "instruction centered" paradigm, to a "learner centered" one. In a collaborative learning environment the shift is away from the search for "a" truth, to the recognition of truth and meaning as socially constructed, resulting from an understanding of history, the boundaries of geography, membership, and reflective analysis.

Any discussion or analysis of learning communities, collaborative learning environments, or democratic classrooms found on the Internet or not, is not a simple matter. Any discussion of collaborative learning is an analysis and critique of the established discourse and collective consciousness which benefits certain "ways of knowing" and the construction of individuals as objects. To reflect on what appears to be a "common sense" reality of educational practice is as complex as attempting to understand reality from any perspective.

Educational Technology as a Method of Control

In the first part of this paper I attempted to create a framework for considering the notion of the "individual" in education. I would like to now shift our attention to a brief discussion to contextualize the field of educational technology as a discourse of control and benefit. First of all, technology is about systems not objects or devices. Educational technology emerges out of a systematic approach to the identification of educational needs or problems, and their solutions. Educational technology systems frames a relationship between hardware or devices, software-the curriculum, and theories of instruction and learning which also draws from the fields of communication, learning, evaluation, and information design.

Before 1940, various devices served the classroom teacher as an aid to their instruction and as an enhancement to the learning process. Audio Visual aids, or AV, served the classroom teacher in her attempt to bring the world to the classroom, as seen with film and still images (with accompanying sound). Most of devices from this time period were seen as "aids" to the teaching process, not as a delivery system of instruction and the curriculum.

After the 1940s and into the 1950s there was a shift away from audio visual aids to a technology of instruction. Educational technology was a merging of engineering principles and devices – with roots in the social engineering movement of the late nineteenth century; psychology- with its roots in behaviorism, and education given the responsibility of preparing our youth to be productive and participate in the modern world (which usually meant the world of labor), educational technology could provide a scientific rationale and process for making education more efficient, effective, and accountable to the dominant culture and their perception of a good society.

Out of the merger of engineering, psychology, and education, emerged the current field of educational technology. As far back as the first decade of the 20th century we have witnessed the merging of system concepts with educational needs. Taylorism applied to education is a good example of that effort to separate the "conception and development of curriculum" from its delivery in the classroom, as well as the management of the educational factory. In the 1920s and beyond, we find in the work of Franklin Bobbit, WW Charters and others, the efforts to bring a scientific process to the development of curriculum. But it was not till after World War II that we witnessed the emergence of a technology of instruction to address what was seen as the weakest link in the educational endeavor—the classroom teacher.

I feel it is important that we contextualize our thinking about "collaborative learning environments" within this history because it is this history that student centered, collaborative education is in opposition to.

Collaborative Learning Environments

From what I have argued above, collaboration, people working and learning together, is in opposition to a system which constructs individuals as autonomous isolated objects.

How we (the collective we) construct educational environments through the Internet will be dependent upon the paradigm brought to our endeavors. The environment we create will be dependent upon the paradigm we employ, the constructs of knowledge we elicit, and the educational philosophy we practice.

Educational environments created on the Internet will define the individual as either an autonomous agent or as a member of a community of learners. In either case, the nature of knowledge, the vision of futures, and the identity of the self, will be formed respectively. Classrooms located on the Internet or within the walls of the institution will look differently. Each will define through its own framework the notion of legitimate knowledge and what it means to learn.

Issues related to building and practicing collaborative learning environments (communities) begin with opposition to the concept itself. Teachers, administrators, and learners have internalized the dominant definitions of what it means to teach, learn, and hold class. Questions concerning teacher work and student evaluations will arise. Issues related to a fixed or constructivist view of knowledge will need to be discussed and reflected upon. In short, collaborative learning engages the whole notion of what it means to teach and learn. It brings everything into question. There is no safe ground when the status quo is questioned and challenged. A guiding question within the debate will be: "Who benefits from the way education is now and who will benefit if it changes?"

The Internet offers to us who have access to it, a world of possibilities to increase democratic practices and to redefine what it means to teach and learn. A collaborative learning community challenges dominate forms of knowing, allowing those who have been marginalized an equal voice in constructing social reality.

E-Learning: "Self Service" Does Not Equal "Self-Directed"

By Felicity Mulgan
Content Alive
felicity.mulgan@contentalive.com

Abstract: This paper examines the distinction between self-service learning and self-directed learning in relation to e-learning strategies. Based on the findings of a series of case studies of Canadian corporations with e-learning strategies, it argues that e-learning alone is not the solution for businesses that want to nurture and grow their knowledge capital. Rather, e-learning in conjunction with a deliberate strategy to increase employee self-directedness is a more effective solution. It further argues that although traditional e-learning strategies may bring about small, incremental improvements towards greater employee self-directedness, these will only occur on a wider scale if an organization sets out to develop more of what Rosenberg terms a "learning culture" (2001).

Introduction

As more organizations adopt e-learning strategies, training delivery is moving towards a self-service model, where learners are expected to take more responsibility for taking and completing required training.

The self-service model offers many benefits to organizations, particularly in terms of cost and efficiency. Gone are the expensive classroom courses and the costly trainers. Gone are the days when the course schedule determined when training took place, or when enforcing training consistency across the organization was a challenge. Organizations can now administer standardized training from a learning management system, establish job-related curricular, track employee progress and enjoy the efficiencies of disintermediation that e-learning affords.

While benefits like cost savings and efficiency may appear to be worthwhile goals in the short-term, it is pertinent to ask whether the typical self-service e-learning model that business organizations are adopting is really providing them with the learning system they need to meet the demands of doing business in the 21st century. Our series of case studies of Canadian corporations with e-learning strategies suggests that despite implementing e-learning, many organizations still take a traditional approach to training. Our findings also suggest that a key barrier to change lies with organizational attitudes towards learning, and that e-learning in conjunction with a deliberate strategy to increase employee self-directedness is a more effective way to ensure knowledge and skills are developed and shared within organizations.

E-learning Strategies and Self-Directed Learning

Current theories of e-learning identify two opposing paradigms: the traditional approach reflecting a "training culture", where knowledge and skills are transmitted to learners, and the value drivers for the organization are cost, efficiency, access and consistency; the progressive approach reflecting a "learning culture", where learning takes a "transformation" approach, and where the value drivers for the organization are "synergistic", and include the ability to create more self-directedness, build communities, share knowledge capital and integrate employees more fully in the business (Berge 2000, Pearson 2002, Rosenberg 2001).

The progressive approach, it is argued, is a better response to the ongoing social, economic and technological changes that organizations now face. A workforce of flexible, self-managing and self-directed employees is a critical part of this approach. This belief is supported by studies that have found a positive correlation between self-directed employees and improved workplace performance (e.g. Guglielmino & Guglielmino 1988, Long and Morris 1995).

E-learning provides organizations with the means to support and develop self-directedness amongst employees in a way that was never available before, but not all e-learning is created equal in this regard. Within the range of e-learning practices and strategies, it is possible to find both traditional and progressive approaches to training/learning, and to find strategies that are more about enhancing self-service than self-directedness. This is an important distinction to make, since self-service and self-directedness meet different organizational needs. The former is a method of administering learning that cuts out the "middle man", and provides some flexibility to learners within an ultimately controlling environment. Indeed LMS's can be a boon to organizations that want to tighten control over who learns what and when, and keep track of employee development. The latter, self directedness, means employees play a greater role in shaping their own personal development, setting their learning goals, and managing their own development. It means developing in employees what Senge has called "personal mastery" (1990), and embracing the concept of continuous learning.

To illustrate, many e-learning practices, such as online courses, continue to reproduce the standards of more traditional delivery mechanisms (linear structure, fixed content, completion through a test, etc.), while the typical learning management system perpetuates the concept of training as a series of pre-determined one-time events rather than as an ongoing process that is responsive to individual needs (Harrison 2000). By contrast, e-learning practices that can encourage greater self-directedness have less in common with traditional delivery mechanisms, and include self-assessment tools, performance support tools, collaborative learning spaces, online mentors, online resources, decision support tools, content development tools and knowledge management systems. Used as part of a strategy that encourages self-directedness, they can be powerful tools for both employee and organizational development (Rosenberg 2001).

To understand why many organizations have not adopted the more progressive practices of e-learning, it is necessary to examine the role of self-directed learning in the workplace. Knowles defined self-directed learning as "a process in which individuals take the initiative, with or without the help of others, in diagnosing their learning needs, formulating learning goals, identifying human and material resources for learning, choosing and implementing appropriate learning strategies, and evaluating learning outcomes" (1975). Two concepts here, learner control and learner initiative, have rarely been a feature of workplace learning. However, much of the literature on self-directed learning finds that for self-directed learning to take place, learner control and initiative are among the critical success factors (e.g. Tough 1979, Candy 1988, Guglielmino et al 1988, Morris Baskett 1993, Bouchard 1994). The challenge for business organizations, therefore, is to foster these traits in employees in a way that is meaningful to the success of the organization. This usually means aligning the employees' desire to learn with the goals of the organization.

A useful framework for measuring the degree to which training or learning is self-directed in the workplace is Piskurich's Self-Directed Learning (SDL) Continuum (1994). His assertion that at a certain point along the continuum, the locus of control shifts from the organization to the employee/learner, ties in with the traditional/progressive paradigms discussed earlier. If we analyse the e-learning practices of an organization in relation to the continuum, we can easily identify how far the organization is organized upon the principles of employee self-directedness. The locus of control concept also helps to identify practices that are more about self- service than self-directedness.

Findings of Study

Our series of case studies of e-learning strategies at Canadian corporations looked at how far their e-learning strategies were promoting employee self-directedness. It found that in the majority of cases, the strategies were focused around basic online course delivery, usually via a learning management system. Though these strategies were promoting the self-service model, they were not promoting the concept of employee self-directedness. No practices were identified that belonged far enough along Piskurich's SDL Continuum for the locus of control to have shifted to the employees. A summary of findings include:

- Standard, linear tutorial type courses were most common
- Tutorials were typically presented in 30 minute or longer chunks of information at the subject or competency levels, rather than at task levels
- Courses were expected to have a shelf life of over a year, so were not always tailored to immediate needs
- Courses had associated tests; passing a test was deemed to indicate that the skill or knowledge had been acquired
- No specific training or tools were offered to help employees become more effective learners
- Training interventions were limited to job-related skills and knowledge

- Opportunities to take training outside a job-related curriculum were almost non-existent
- Employees were rarely able to identify own learning needs
- Knowledge management or knowledge sharing was either not practiced or was in its infancy, and took on a "push" characteristic, not a shared characteristic

An investigation into the culture and attitudes towards learning at these organizations further underlined the finding that these organizations were promoting self-service, rather than self-directedness. In all cases, although learning was considered a strategic necessity, it was also considered distinct from productive work, and was therefore thought of as an organized type of activity that employees participated in, rather than as an integral part of work that could happen at any time, with any one. These organizations were only prepared to sponsor or underwrite learning interventions that could be clearly linked to specific job skills, and all personal development was tied strictly to an employee's current position or to the development of skills in preparation for a particular career move. Employees were offered virtually no e-learning opportunities to explore other avenues of knowledge, particularly those that had less direct relation to the organization, and there were no examples of the use of e-learning practices such as collaboration, two-way knowledge sharing, and other methods associated with the progressive paradigm. Although the implementation of LMS's had successfully reduced the gate-keeping role that managers used to play in relation to employee training, managers continued to set work priorities and remained strongly focused on traditional notions of productivity, which were seen as distinct from learning.

On a more positive note, our study also found signs that employees appreciated the independence that self-service learning gave them. Other small, incremental changes in relation to self-directedness were also discernible, which may lead to greater expectations of learner autonomy in the future. At the more senior levels, employee expectations around personal development were also found to be high, and organizations were thus under pressure to provide more access to training and learning opportunities. This reflects a more general trend identified in relation to employee training and retention (e.g. Moss Kanter 2001), and one that is likely to trickle down through all levels of the organization as the population in general grows used to being able to find the information it needs online.

Conclusion

A workforce of self-directed learners is an asset to an organization that wants the flexibility to respond to the pressures of today's economy. However, self-directed learning is partly about control: who controls what, when, how and why an individual learns, and who determines whether they have reached an appropriate standard. Currently, e-learning strategies appear to mirror the culture of the organizations in which they are implemented, particularly in terms of who controls learning goals and resources. The results of this study of a sample of Canadian organizations suggest that the implementation of e-learning does not, in itself, transform an organization from having a training culture to a learning culture. Despite e-learning's potential to change the way employees learn, e-learning is viewed by some organizations as a cost efficient alternative delivery mechanism rather than a vehicle to overhaul approaches to learning, and control over learning goals and resources remains firmly in the hands of the organization.

Organizations such as those featured in this study may be missing opportunities to develop a more flexible, self-managing, self-directed workforce that can respond effectively to ongoing change. All those involved in developing e-learning strategies, from training managers, to e-learning vendors and consultants, can play a role in helping organizations see that e-learning is not a homogeneous solution to training a workforce, and that sometimes more fundamental organizational changes need to take place in order to develop the best and most effective employees.

Questions and Answer (query, reply, question and response): Lecturer often interacts with students by verbal communication in the lecture. We call this part "questions and answers". We classify this part into four parts in detail. When speaker is the lecturer, we define as "query" and "reply". On the other hands, when speaker is a student, we define as "question" and "response".

3. Experiment

We have practiced TIDE (Trans-Pacific Interactive Distance Education) project between University of California Los Angeles (UCLA) and Kyoto University (Yagi et al., 2000, Murakami et al., 2001).

"Japanese Economics" were offered from April to June 2001. Several professors of Kyoto University give this course. For Kyoto University students, this lecture is regarded as usual multimedia lecture. In this research, we select this distance lecture as experimental lecture.

Figure 2 shows the figure of classroom of Kyoto University. Left screen shows Web material, and right screen shows students of UCLA. Lecturer makes the lecture on the center of the classroom. In this situation, students' eye movement changes depending on what they look at, among lecturer, students of UCLA on the screen, and material. Two cameras in the front of classroom recorded students so as to catch the direction of their eye movement. Whereas the camera behind the classroom recorded lecturer and two screens in order to check the contents of lecture. And, the first author attended all lectures and recorded the state of classroom in field notes. After that, we classified the recorded lecture into instructional process category.

We select two lectures as experimental lectures among course. Two lectures were practiced by different lecturer. Table.1 shows time of each category.

We extracted 9 students from each lecture as target of analysis. We checked what students look at per 10 second. Additionally in order to analysis in detail, we select some parts of lecture, which cover all categories, so we checked per second about the select data.

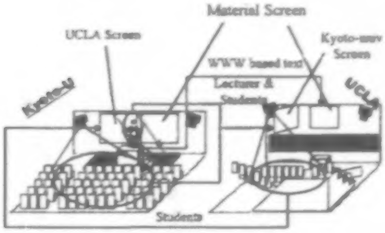

Figure 1 Distance Lecture System

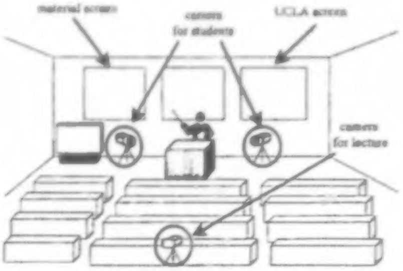

Figure 2 Classroom of Kyoto University

Table 1 Time of Each Instructional Process Category

We consider ratio of observation and pattern of eye movement as indicator. The ratio of observation is calculated by (the number of students looking at the object)/(the number of all students). The pattern of eye movement is based on cycle of eye movement and what student looks at first. We define cycle of eye movement as (when he/she looks at lecturer) + (when he/she looks at material next), or in the case of reverse order. We think that the continuous is important factor, so that we analyze the data by the following methods. If student looks at different object in only a second (for example, lecturer in 3 seconds, material in 1 second and lecturer in 4 seconds), we regard that student looks at same object continuously (above example, lecture in 8seconds).

4. Analysis

4.1 Result

	introduction	presentation	explanation	illustration	Assertion	query	reply	Question	response
lecture1	4:30	11:10	18:30	4:30	8:30	0:30	7:10	7:20	1:40
lecture2	4:00	20:00	12:30	9:40	5:20	2:00	5:30	4:00	3:00
Average	4:15	15:35	15:30	7:05	6:55	1:15	6:20	5:40	2:20

BEST COPY AVAILABLE

Firstly, in order to clarify the character of ratio of observation on each category, we calculated average of the ratio of observation per 10 second on each category. The result shows Table 2.

Table 2 Ratio of Observation on each Instructional Process Category

	introduction	presentation	explanation	illustration	assertion	query	reply	question	response
material	41.3%	81.3%	50.1%	93.5%	24.3%	22.2%	8.6%	6.6%	4.5%
lecturer	47.9%	17.4%	48.0%	6.5%	71.2%	57.8%	59.3%	20.3%	37.7%
students	10.8%	1.3%	1.8%	0.0%	4.5%	20.0%	32.1%	73.0%	57.8%

Secondly, we analyze eye movement of each student on each category. Results of analysis about introduction, presentation and explanation show figure 3-5. In these figures, 2 of y-axis shows looking at lecturer, 1 shows material and 0 shows no object.

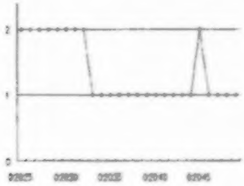

Figure 3 Introduction

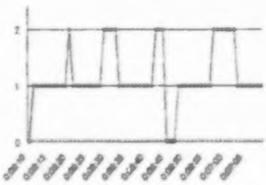

Figure 4 Presentation

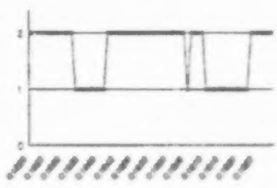

Figure 5 Explanation

Thirdly, we sampled cycles in these data, and add up them on each category. Histogram of cycles about presentation and explanation show figure 6,7. The x-axis shows time of cycle and the y-axis shows the number of times. The average of cycle of presentation is 11.60 second and standard deviation is 3.38, whereas the average of cycle of explanation is 20.21 second and standard deviation is 6.85.

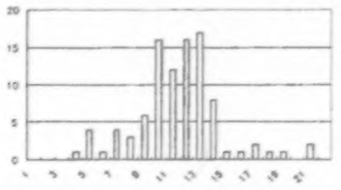

Figure 6 Cycle about Presentation

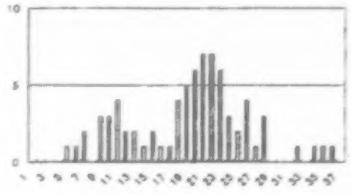

Figure 7 Cycle about Explanation

4.2 Relation between Category and Eye Movement

We discuss the relationship between instructional process category and eye movement from the results of analysis described in 4.1.

Introduction: The ratio of looking at material is much the same the ratio of looking at lecturer from Table 2. As concerns the pattern of the eye movement, students gazed at lecturer at first, and next looked at material from Figure 3. It is thought that they tried to acquire advance organizer from the lecturer.

Presentation: The ratio of looking at material is very high, 81.5%, from Table 2. From Figure 4 and Figure 6, students mainly stared at material for about 15 seconds and sometimes peered at lecturer for about 3 seconds. They learned of multimedia material during presentation, so that they mainly stared at material. And they looked at lecturer in order to complement understanding.

Explanation: From Table 2, the ratio of looking at material is close to the ratio of looking at lecturer. From Figure 5 and Figure 7, the cycle of eye movement is about from 19 seconds to 29. The cycle is the longest than other course process categories. They learned from multimedia material during explanation, so that students stared at the object which they regard as important to understand the lecture.

Illustration: The ratio of looking at material is the highest, 93.5%, from Table 2. As the reason of high ratio, it is thought that material offered main information source.

BEST COPY AVAILABLE

Assertion: The ratio of looking at lecturer is very high, 71.2%, from Table 2. They gaze at lecturer because of interaction between lecturer and students.

Question and answer: Generally, students looked at speaker. But in the case of "query" about material, they change their focuses on material and lecturer by turns frequently. It is thought that students tried to grasp information of lecturer and material in order to answer to the question.

4.3 Guideline

Based on the result of analysis, we discuss the practical guide for select of image information. In introduction, we should select image of lecturer for several seconds first in order to give advanced organizer. In presentation, we basically select image of material, but we occasionally insert image of lecturer. In explanation, we should present image of material and lecturer by turns for about 20 seconds. In illustration, we should select image of material. We should select image of lecturer in assertion. In questions and answers, we basically select image of lecturer, except the case of the query about material. In query about material, we should alternate image of lecturer and material frequently.

5. Conclusion

In this article, we report our analysis about relation between the contents of lecture and the students' eye movement in order to clarify the criterion to select image information for distance learning and WBT. As the result of analysis, we get the characteristic of students' eye movement in each instructional process category in practical lecture. And based on these results of analysis, we propose to apply these results to selecting image for distance learning.

ON-LINE STUDENT SUPPORT SERVICES (OSSS)

A Pre-Testing Opinion Survey of Distance Learners on OSSS

Dr. K. Murali Manohar
Professor of Distance Education and
Programme Director, DEQSTI, SDLCE
Kakatiya University, Warangal (AP) India

Distance Education (DE) is known for its 'learner-centeredness' and precisely due to this reason it evolves and provides all possible support services through every possible means to facilitate the learners complete their 'learning objectives'. Most of the DE institutions provide a wide variety of support services to reach each and every student based on their needs and requirements. The institution may use print or telephone or other mode to interact with the students for various purposes ranging from providing information and other services from pre-entry level to post-entry to after-course completion levels. The students under distance mode of learning will naturally seek endless information raising a number of questions, doubts and various other queries time and again till they get satisfied. In the recent times most Universities are found to have been using Internet and web technologies to maintain on-line communication with the students.

In a traditional system of ODL, there will be a Reception / PR Centre or Academic Services Division which would deal with the academic questions and problems of students and resolve them instantaneously on its own or by referring to the administrative units concerned. In a modern ODL system instead of doing these activities manually or through correspondence, it will provide the services concerned through electronic means via website. Under this system each University will have an interactive website while facilitating the students to have exclusive access to the On-line Student Support Services (OSSS) system. It would provide access to students via Internet about any information (being updated every time) regarding the courses and programmes available, with full particulars and details of eligibility conditions, academic schedules, fee and its procedure for payment including on-line payment of fee via credit card, submission of receipts, confirmation of admissions or cancellations, academic counseling, information relating to Regional/Study Centers and their activities on-line chat rooms with faculty members involved instructional materials (with down loading facility), assignments, feedback forms, news letters, student forums, all types of academic time tables, results, grades, marks, certificates and messages relating to deadlines, general information and other academic details in which the students may be interested to know or the institution may be interested to make others know.

The system can provide all possible information, clear options, needed access with 'dos and don'ts' or 'proceed or do not proceeds' and other instructions and instantaneous resolution of problems and 'on-line acceptance or rejections' with full opportunity to students to continuously interact, make alterations needed and get other related things done. It will provide access to services while increasing one to one interaction and enabling self-based learning. Further it gives complete security of information and protection from hackers on on-line transactions with student access No. and password facility to activate the system any time, from any where and for any purpose and facilitating the students to seek needed support and guidance at all levels of their study. There will be automatic mail-back system, messaging, remainders to students e-mail account, auto-reply system on all simple and programmed queries, answers to any general or specific or frequently asked questions etc. At appropriate levels and stages, audio and video facility also will be made available for appropriate institution - student interaction. As things move and as facilities improve more and more information could be added thereby and the OSSS system is continuously upgraded and strengthened. The institution under this system may provide free Internet access points in all Regional and Study Centers or at appropriate places where study centers are not available for student free access and use and this will relieve the student's burden. Since the Internet facility is available everywhere and in every town and city and not being very expensive in the open market, more and more student's 'will come forward' to use it. Provision for a little more skill or training can make the student more perfect in 'accessing and approaching' the institution by activating the OSSS. This system is new to Indian ODL institutions and except to some extent at IGNOU, a few IITs and other technical institutions which provide distance mode of education, no full-fledged OSSS system is now available any where in India's University education system. Thus the introduction of OSSS in any University system in India would still be an 'experiment' and in this connection Indian ODL Institutions are to learn many lessons from the experience of advanced institutions.

Present Study: 'The What and Why' Issues

The present study deals with the concept and a model of on-line student support services system (OSSS) and makes an attempt to elicit student's opinion on a programme specially proposed (at the pre-introduction-level) of an on-line student support services system at a 10 year old Duel Mode University operating in Southern part of India with 62 programmes (from Certificate level to Ph.D. level) and 36,000 students to its credit. It has already setup a website and permitted students to seek answers from the institution through e-mails. It is found that an estimated 30 per cent of post-graduate students had e-mail account and interestingly eighty per cent of them had the account with yahoo.com, around 12 per cent in their offices, 2 per cent in their homes and the remain with other companies. It is estimated that to create and setup a dynamic website with necessary staff at the Head Quarters and Internet facility along with necessary equipment in around 50 study centers it will cost a one-time capital expenditure of around Rs. 20.00 lakhs and an annual recurring expenditure of Rs. 8.00 lakhs which is in any case not a burdensome proposition to the institution which had Rs. 600 lakhs annual revenue income to its credit. The institution under reference recently took a decision to introduce the system and hence the survey to know its feasibility.

The University under reference thus based on its proposals to introduce a system called OSSS, a 'pre-induction' survey has been conducted both by using electronic mail and printed questionnaires while contacting 300 students via e-mails and 300 students by pre-paid postal media for collecting their opinions and responses on various connected issues of 'creation, induction and implementation of OSSS scheme'. For the purpose of the survey, all the respondents chosen were drawn from urban and semi-urban areas pursuing post-graduation courses through distance mode. The response rate is relatively high through electronic media (about 212 out of 300) which is a healthy sign as far as the 'introduction of the proposed system' is concerned. About 180 (out of 300) responses were received by postal means which is also not much discouraging. The responses indicate that students seem to have felt very much happy for approaching them and showing concern like this and extended full cooperation to respond to a wide variety of questions with a feeling of involvement and a sense of responsibility. To be straight and brief, the main results of the survey are summed up below while highlighting various aspects covered.

Availability of Internet Facility

An overwhelming majority of students as around 82 percent (95 percent of Internet users and 62 percent of correspondence respondents) had said that Internet facility is available in their places and they are for introduction of OSSS response system in the University. Most of them however pleaded that 'free Internet access' with a little training for handling it may be provided to them and all study centers/regional centers/ other centers may extend such services to all the bonafide students. Further 18 percent of the students had already had the Internet facility in their homes/offices which they can make use of and around 30 percent of the students had the experience of using Internet earlier for different purposes.

OSSS and its Need

An overwhelmingly 88 percent of students supported the idea of OSSS, provided it does not effect the prospects of other support services and replace the old one. Almost all the respondents believe that Internet is increasingly a fast penetrating medium replacing the phones, fax and mail as a preferred method of communication and offers quick, easy, powerful and timely response to the users. It is significant to observe that most of the students had already had some idea about the on-line services available 'outside' and in different western universities. A majority of them have had the access to different computer and Internet magazines and through which they had learnt the benefits of the system. Most of them had even developed a liking for the system.

Coverage of OSSS

Majority of respondents had felt that OSSS scheme should offer a package of services that should be comprehensive enough to cover the entire gamut of support they needed. Coupled with the facilities already available at study centers, they think that it should serve as a 'full-fledged information support system' to be guided constantly by the 'net'. They said that 'individualized redressal of grievances' and 'a continuous and active flow of information' is possible through OSSS. Thus, apart from serving the purpose of an 'information provider', OSSS system may also offer the facility of processing and confirming admissions, accepting credit card or on-line payments, making needed altercations of programmes / centers / combination of courses, supply of additional instructional materials other than the course materials supplied available as well as on-line, in print form, handling assignments, declaration of results, providing score cards, marks sheets etc., the respondents added. It should otherwise provide a virtual campus facility keeping in view of the changing needs of the students on the one had and encouraging creativity, independent thinking and problem solving on the other.

Cost Component

Majority of the students however seem to have 'vigilant and cautious' as far as the matters relating to the 'cost component' is concerned. A vast majority of the respondents said that it should not involve any additional cost on their part and impose any additional financial burden to meet the expenditure towards this purpose. More respondents who had no Internet accessibility at home and office, pleaded that necessary equipment must be provided at the study centers with full and free accessibility of the net service. They should also be provided a minimum knowledge of technology - both hardware and software in a specially conducted induction programme.

Some Apprehensions

In the overall analysis, though a couple of apprehensions were also raised especially about the need for increased access to technology, increased speed in connectivity, greater-band width, its relevance and applicability to all courses, availability of required hardware and software at the study centers, data up gradation and improvements, promptness of service and quality of maintenance of OSSS system, there is widespread agreement on the need for such a support service.

Implications and Conclusions

On-line delivery of support services making use of new information and communication technologies has a lot of potential for providing quality and prompt on-line support service to the students. The response from the students towards the need for a system called OSSS is overwhelming and they were willing to accept the use of Internet and web technologies for strengthening the institutional student support system. Since Internet facility is available everywhere in the open market with costs decreasing, it appears that provision for OSSS in any University and especially the University under reference is feasible and manageable. the willingness and commitment on the part of the institution to strengthen the student support services and its level of efficiency in managing it would give greater results for the benefit of both the institution as well as the students. But the issues relating to the cost component and preparedness of the ODL institutions to provide the service, provision for necessary budgetary allocations, creation of additional inputs such as expertise to man the service and provision for machines at the HQs and study centers etc., still, remain matters of serious concern for the institution to offer. The whole programme seem to be still dependent upon various other factors such as the design, facilities and maintenance of the website of the institution, the bandwidth, greater penetration of information and communication technologies, greater access and increased speed in connectivity, openness to cultural variables affecting the machine-human interactivity etc., still remain as crucial issues. In spite of all these, the positive results of the feedback from the students provide a valuable data on how these programme could be introduced and implemented with facilities available outside and in the open market, costs decreased and access increased, coupled with appropriate and

2019

need-based changes in the whole programme, introduction of OSSS will be of great use to the students and provide a strong base for a complete on-line education in the near future.

Internet-based Distance Learning in Slovakia

Klara Nahrstedt*, Julius Bajcsy**

(*University of Illinois, USA - klara@cs.uiuc.edu, **Slovak Technical University Bratislava Slovak Republik - julius@pluto.elf.stuba.sk)

Abstract

Many universities in USA, Canada and West Europe have extensive experiences in offering distance education courses to remote students and utilize the advanced Internet and multimedia technology for appropriate interaction. In Eastern Europian countries, the Internet-based distance learning programs are being setup only recently, however for different reasons and under different conditions when compared to programs in Western Europe, Canada and USA. Having learned from past experiences of Internet-based distance learning programs at top ranked universities around the world, we present a design of an Internet-based distance learning program for technical universities in Slovakia. We discuss the overall design process through the case study program, initated at the Slovak Technical University in Bratislava.

1. Introduction

There has been an explosive growth of multimedia computing, communication and educational applications during the past years, extensively utilized in Internet-based distance education at various universities (e.g., University of Illinois, Stanford, McGill). Internet-based distance education represents an educational form where students are located outside of the classroom and reach educational material as well as the instructor via remote multimedia electronic tools such as video conferencing such as NetMeeting from Microsoft, Web service, email, ftp service, and others. Current computing and communication environments, consisting of high-end PCs, cable modems, Ethernet LANs, or DSL communication lines, at many universities and homes allow for interactive communication and on-demand multimedia information access. Instructors of distance learning programs are able to (1) distribute their teaching material, auxielary papers, detailed instructions to the remote students via web, email, ftp services, (2) receive comments, and questions via email and newsgroups, and (3) conduct discussions via newsgroups and other chat programs. Remote students of distance learning programs are able to (1) access all teaching material remotely through web services, and other Internet services, (2) communicate easily with instructors and their local student fellows, and (3) conduct remote experimentation, using expensive equipments on the campus, during their laboratory work.

Many universities in USA, Canada and West Europe such as Open Universities (e.g., in England), Stanford, UIUC, McgGill, and others, have extensive experiences in offering distance learning courses to remote students in other countries and utilize the advanced Internet and multimedia technology for appropriate interaction [1,2,7]. However, many top ranked universities have also reserved attitude about offering distance learning programs such as master programs to remote students in foreign countries [3]. In Eastern Europiancountries, the Internet-based distance learning programs are being setup only recently, although for different reasons and under different conditions when compared to USA, Canada, and West Europe. Having learned from past experiences of Internet-based distance learning programs at top ranked universities around the world, we present a design of an

Internet-based distance learning program for technical universities in Slovakia. We discuss the overall design process through the case study program, initiated at the Slovak Technical University (STU) in Bratislava.

The paper outlines in Section 2 the history of distance learning at STU in Bratislava. In Section 3 we present the goals, justification and implementation of the Internet-based distance education program at STU, and in Section 4 we discuss organization and business issues of the distance learning program . Section 5 concludes with leassons learned from other distance learning programs that will be seriously considered during the execution of the STU experiment.

2. History of Distance Learning at STU

Distance Learning at STU in Bratislava has a long tradition and history [4,5]. The first form of distance learning program started during the school year 1952/53 through the Resolution of the Slovak government about extraordinary forms of study, November 11, 1952. The department of Electrical Engineering at STU established the Consultative Center for Remote and Evening Study, which was directed by the Institute of Remote Study at STU. In 1956, the organization and control of the distance learning programs was moved from the Institute of Remote Study to the departments (to the associate dean for educational technologies).

The distance learning program took on three different forms:

- **Six years distance learning undergraduate study** (during 1983/84 this program was renamed to Distance Learning on the Job). The student was able to finish the first two years of study any time in consultative centers, established outside of the university.
- **Six years evening dstance learning undergraduate study.** This study was organized and possible for resident students on the campus of the university who worked during the day and took classes during the evening hours.
- **Three years specialized suplement distance learning study for teachers of secondary teachnical trade schools.** This program started in 1976/77.

All three forms of the distance learning program required that the students met twice a month with the instructor (Friday and Saturday), as well as at the end of the semester, they would go through laboratory exercises of courses that required experimental skills. The students of these distance learning forms used the same lecture material, such as books, papers, provided by the instructor, as the regular registered students on the campus. The last set of students who graduates via these distance learning program forms graduated in 1994/95.

3. Internet-based Distance Learning at STU

The goal of the Internet-based distance learning program at STU in Bratislava is to provide undergraduate bachelor degree to remote students outside of STU and Bratislava. There are several reasons for the demand of Internet-based distance learning: (1) For many students outside of Bratislava, the **cost of living** in Bratislava is too high; (2) There is an **acute shortage of professors and teachers** in technical disciplines at technical universities outside of STU; (3) The **cost of traveling** for teachers and students is very high; and (4) The **equipment budget**, universities receive from the Minis tery of Education, is very low, therefore sharing and remote experimenting with expensive laboratory equipment is neccessary. Hence,due to the reasons above, and due to the modern Internet-based technology development, which allows not only paper material distribution, but also interactive electronic communication (e.g., email, web service, multimedia conferencing) with remote students and remote experimentation with laboratory equipment, the distance learning program at a new level is neccessary in Slovakia. In 2001/2002, the Department of electrical engineering and information technology at STU[1] in Bratislava started to offer an undergraduate degree via Internet-based distance learning program in the area of electrical power engineering. The department plans to expand the areas and to offer an undergraduate degree in the area of automation in 2002/2003.

To implement successfully the distance learning degree programs in power engineering and automation, the STU set up three local centers for distance learning throughout Slovakia in Bratislava, Zvolen and Kosice six years ago. These centers were prepared and participated in the development of the technical infrastructure, needed for Internet-based distance learning. The material and technical infrastructure setup were strongly supported by international projects TEMPUS, PHARE and LEONARDO [6]. The centers gained alot of experiences by organizing various preparation courses for entrance exams in the area of mathematics, physics and chemistry, as well as provision of courses in industrial management.

4. Organization and Financial Support of Internet-based Distance Learning at STU

For a student to complete the undergraduate degree via the new Internet-based distance learning program, it is planed to take six years. The first two years of the educational plan are already clearly outlined, and plans for the next four years are in preparation. Long-time experienced teachers are contracted and are working on creating the electronic and traditional educational material for the Internet-based program. The requirement is to deliver the requested educational material to the centers one year before teaching of the course is offered[2].

The remote students receive advising and other help for their course work through Internet-based communication with the course instructors directly or through Internet-based communication with the teaching assistants assigned to the course. All teaching personel in the Internet-based distance learning program is contracted and the conditions for usage of Internet services when communicating with remote students are clearly defined, including financial agreements for performed activities.

The financial support for the Internet-based distance learning program comes from three sources: (1) **fixed cost** for creation of the teaching material, honorarium for authors/instructors, and financial support for acenter comes from the internal departmental budget, which is given to the department by the Ministery of Education according to the number of students (Undergraduate degree for every student is paid by the Slovak government), from sponsorship donations, and from international projects; (2) **variable cost** for written material, mail, telephone cost and others come from the students who purchase educational material; and (3) **other direct cost** for equipment, used in laboratories, comes from the departmental budget.

5. Conclusion

The Internet-based distance learning in Slovakia is in progress and it is now matter of time to show its successful path as well as lessons learned. The program was established on sound base of many experienced international programs[1,2,4,6,7], hence there is an optimism that this distance learning effort will (1) **save the living and**

---

[1] In Slovakia, the official name for the Department of Electrical Engineering and Information Technology is the *Faculty of Electrical Engineering and Information Technology*.

[2] The material, delivered one year ahead, is only conceptual material, not the final electronic delivery format.

transport cost of many new students, (2) **address the current shortage** of instructors and teachers at technical universities in Slovakia, and (3) **allow students to share** expensive and advanced laboratory equipment via Internet-based technologies.

Putting the E to Work in E-teaching

John C. Nash
School of Management
University of Ottawa
Canada
jcnash@uottawa.ca

Abstract: We consider university teaching from a viewpoint of the activities in which students and professors engage while taking or giving courses. We seek to apply software and procedural tools to make these processes more efficient, following in general terms Deming-style process improvement. Our ultimate goal is to have technology that is so familiar and obvious that students and professors use it naturally without training. Tools we have developed or improved to date include homework submission (with identification and automatic routing by section), random "volunteer" selection (PICKSEAT), image grab and send, a simple web forum for consolidating student and professor contributions, and image consolidation and captioning. None of the above tools is new in concept, but we believe there are important benefits from the level of simplicity achieved.

Motivations

In teaching statistics to business students, we have found it highly effective to "teach from the back of the room", even in classes as large as 80 students. This tutorial style allows the professor and other students to witness mistakes or gaps in student background and provides an opportunity to correct the deficiencies. At the same time we show that problem-solving requires a willingness to learn from mis-steps. We would like to adapt this teaching style on the Web, especially if the sessions could be saved for replay as web-pages. To limit resource demands, we seek a low-bandwidth solution. We also want system components to be useful in themselves so that we can use developed software as soon as possible, in particular to deal with the province of Ontario "double cohort" (www.occta.on.ca/pdfs/ontdblcohort.pdf). The components described below may succeed even if the totality, named *E-tutor*, does not.

Consider the activities in which students and professors engage while taking or giving courses. From this viewpoint, we seek to apply software and procedural tools to make these *processes* more efficient, following in general terms Deming-style process improvement. "Efficient" in our context is measured by comparing the relative or marginal time, effort and resources needed to accomplish a given task in different ways. That is, we accept existing infrastructure as given and apply relative costings. Our ultimate goal is to have technology that is so familiar and obvious that students and professors use it without training and without taking particular note of it. Some of the tools we have developed or improved to date include:

- File uploading by students for homework submission and subsequent downloading or retrieval by the professor or teaching assistant. The software must modify file names to identify the student and also permit block download by the professor or assistant.
- Choosing a "volunteer" to solve a problem in class (PICKSEAT) in a way that is random so that there is no favouritism or victimization.
- A web forum to allow students to pose questions and/or answer queries by others (CO4).
- Image grab and send (ET-GRASED), needed to allow a student to communicate written or drawn material to the professor and the class, since at low-bandwidth we do not wish to use video.
- Simple web forum for consolidating student and professor contributions.
- Image consolidation and captioning.

None of the above tools is new in concept, but we believe the level of simplicity we have achieved – by efforts that belie that ultimate simplicity – has been worthwhile. Moreover, the tools are usable alongside or within other e-teaching systems and will be made available under an open-source licence. We intend that they be consolidated into the full Etutor system, which is the long-term objective. The design for Etutor was proposed by the author in 2000 and reviewed and assessed in early 2001 (K. Leblanc, 2001). An exchange of ideas with other practitioners, particularly those whose starting point is pedagogy, is welcomed. In the spirit of continuous improvement, we consider all our efforts to be in a state of development.

Experience to date

The School of Management has operated a simple file archive (called DocDepot) since 1999 which has proved extremely useful for supplying information to students on a full-time, 24/7, basis. It has been very popular among students. For example, it eliminates much of the concern about lost or misplaced course outlines or assignment documents, and saves students travel time and parking costs to obtain such materials. Indeed, the success of DocDepot has raised student expectations so that professors are essentially forced to put materials there. However, we still need better mechanisms for upload, control, and deletion of files by professors and others in a sensible manner.

DocDepot has allowed the posting of student work. Students may read and learn from others, and are encouraged to cite any ideas they use. Marks are *not* included, but students quickly judge which work is good. While not provable, we believe posting all work provides a brake on plagiarism. Work that we would term a "disaster" due to misunderstood assignments has largely disappeared. We have observed the incentive to excellence a couple of good papers provide.

Delivery of assignments is therefore an important task. In large, multiple section courses, delivering the student work to the right marker, with proper identification, is an annoying clerical task that creates many difficulties. Homework uploading, with proper sorting and identification, has proved very helpful, and much simpler than either email or diskettes. We have now used a simple file uploader in roughly twenty tasks across a variety of courses plus the first round of the 2001 National Advanced Technology Management Competition, where the competitors were geographically distant.

Students submit material in Adobe Acrobat format (PDF files). We provide documentation and links so such files may be prepared without the need to purchase the Adobe Distiller or PDF Writer. The major advantage of such files is that they are not dependent on the printer definition used in document creation. The marker reads the document (either on-screen or printed out) in the layout and style that the student prepared. Two particular features of our homework submission tool(s) are worth mentioning. One is that the student log-in provides the student number, and this is pre-pended to the filename of the submitted file so that "noname" assignments are not possible. The other is that the marker can choose to download all the submitted work for a given task as a zip file. This saves time during downloads.

Overall, both students and professor have been very happy with the submission tools. Students can work from home, saving time as well as travel and parking costs. The professor similarly does not have to travel to retrieve submitted homework. We found that the typical cycle time from submission of homework to reporting of marks to students dropped by a factor of three. Students had positive comments about this. To date, we have had very few technical problems. Indeed the major "glitch" concerned omission of student names from class lists provided by the administration, so a couple of students could not log in.

Students generally are reluctant to step forward to attempt the solution of a problem. To choose a volunteer" in a way that is random, PICKSEAT was developed. It requires the seat arrangement for each classroom to be set up as a simple character graph in an ordinary text file. If a chosen seat is empty, we proceed to the (professor's) right and then forward row by row until an occupant is found. The program is executed on the classroom display computer. Students seem to regard it as a sort of game, and acceptance has been smoother than anticipated.

Automated consolidation and captioning of images is useful in building some teaching and related materials. We first developed FOTOHTML for use in organizing family photographs in a large genealogical collection. We found it particularly important that the tool assist in verifying that both the image collection and caption list match properly. It is also helpful that the resulting HTML files each display a small number of images (default 10) so the files do not take too long to load in a Web browser.

Other tools are still undergoing tests, but we hope some results will be available by October 2002.

Methods and approaches

We have been developing two variants of the homework submission tools: ETPRL, a tool to handle just one assignment or task, implemented as simple scripts in the Perl programming language, and ETPHP, which is programmed in the PHP programming language and makes calls to the MySQL database system. So far, all experience has been with versions of ETPRL. A design requirement is that the system be very simple and obvious to use, that is, that the affordances of the user interface be intuitive (Norman, 1990 and 1992). For students such clarity has been achieved. The major deficiency discovered was that each task required a separate set of directories and files for both the programs and uploaded files, making setup awkard as well as inefficient of disk space. This is being rectified by the author and a new, streamlined version is undergoing tests.

The CO4 collaborative web forum was programmed in Perl for a Windows web-server by a student, Lawrence Taylor, as a course assignment. Using a general set of requirements provided by the author, he did an outstanding implementation. CO4 allows a set of users to collaboratively build a web page by inserting, adding to or editing sections. There are facilities to insert images or more general file links. The file display is set up to display only a few sections at a time to reduce the time to load the page. CO4 proved quite easy to port to Linux, but so far is lacking in access control. We intend to re-implement in PHP for easier maintenance.

All these tools are implemented using server-side scripts and a single cookie. They are largely unaffected by the firewall protections that were increased after September 11, 2001, while systems relying on client-side scripts have been blocked. Such systems include the WebCT e-teaching system, as well as Hotmail and similar email hosts.

Image grab and send (ET-GRASED) is a tool needed to allow a student to communicate written or drawn material to the professor and the rest of the class. This tool has been developed to the stage of proving capability. The client program is for Microsoft Windows only and written in Visual BASIC, while the server software is a script in PHP for Linux-based servers.

PICKSEAT is already available as a project within the sourceforge system (sourceforge.org) , while FOTOHTML can be obtained via a link from www.nashinfo.com. Both are written in Pascal; while Turbo Pascal was used for development, we believe Gnu Pascal will compile and run these codes.

Future developments

We plan to use ETPRL and/or ETPHP in courses led by professors other than the author, so that reaction and ease-of-use for professors and teaching assistants can be verified and, if necessary, improved. We also hope to launch some trial applications of CO4. PICKSEAT and FOTOHTML are already available to others, but we have had very little reaction communicated to us yet.

We decided very early in the design to release the "products" of the work reported under either the Gnu Public License (www.gnu.org) or similar arrangement. This means that others may use and improve the software, with resulting improvements themselves being available to others. To alert others to this work, and also to learn what choices are being made elsewhere, the author has actively sought to meet workers with similar interests. These exchanges, carried out during personal or professional travel, as well as by telephone and e-mail, have proved very helpful in refining ideas and in gauging the value of design choices. Very recently (April 2002), it has been possible to let such colleagues actually test prototypes of some of the tools. For the most part, the reaction has been exceedingly positive, but it has also revealed some potential improvements and possible "glitches" related to as-yet-unresolved issues with particular Web browsers on particular operating systems.

Conclusions

The tools described above have largely met their design goals. For example, the assignment uploaders have proven very simple for students to use, to the extent that they are almost "invisible". They shorten the waiting time for the professor or marker to receive student work, offering opportunities for quicker correction and assessment that students appreciate. There is also a reduction in the clerical effort of the marker to organize and file papers, especially if students have omitted identification. All the tools are small and relatively simple in design and implementation. Improvements are clearly possible and desirable, but at present we perceive none that require major reworking of the programs.

Acknowledgements

A Teaching and Learning Grant from the Centre for University Teaching of the University of Ottawa paid for programming by Patrick Suwalski and Markus Svilans. Lawrence Taylor and the author also contributed code. Woody Suwalski supplied the Rebel Netwinder server used in initial experiments of ETPRL, while the School of Management has provided innovation funds for the courses.gestion.uottawa.ca server that will be hosting ongoing tests.

Abstract: This project was developed to provide a roadmap for setting up online courses. A series of workshops was designed to help instructors improve upon and expand their use of technology as an instructional tool. Topics included pre-course development, interactivity, converting a traditional course to an online format, assessment, and using web-based materials to supplement a traditional course. Through the use of a web resource, material from these workshops is accessible to anyone interested in developing an online course or supplementing a traditional course with online materials. As a result of this project, 43 of the 47 participants surveyed were more likely to supplement their traditional courses with Blackboard and 42 were more likely to participate in the development of an online course.

Introduction

As the leader of Electronic Learning in the state, Northwestern State University of Louisiana encourages its instructors to make course offerings available online and to integrate technology into traditional classroom courses. The goal of this project was to provide face-to-face and online support for instructors whether they were already working with an online or hybrid course (traditional classroom with online supplements), or just starting to explore these instructional media. While technical aspects of the program were based on a Blackboard platform because it is the platform currently utilized by our university, much of the information can be used with any electronic learning platform.

The Program

A cohesive program of five broad topics was identified as essential to electronic instruction. Six experienced faculty members were identified to present workshops as part of a professional development series on integrating technology and education. These peer mentors were all seasoned veterans in the area of electronic learning, including online and hybrid courses. Faculty members developed a workshop on their assigned topic. Presentations were not limited to a presenter's specific discipline but were developed to be relevant to all participants. Workshops included presentation, group discussion, and small group discussions. Participants were allowed to register for one to six workshops, dependent upon their interest and schedule. Each workshop therefore had to be an independent session but still fit into the overall program. All workshops were presented in the university's compressed video classroom and broadcast via compressed video to two of the university's satellite campuses to allow for broader participation. Two workshops were held each month for three months and a practice course was set up in Blackboard during that time for participants to review examples and practice what they were learning.

Upon attendance at their first workshop, participants began to build their Online Faculty Resource Manual. The manual consisted of a program binder with in-house printed materials for each session, as well as additional relevant materials (tips, guidelines, etc.) to be placed in the appendix. The manual contained a section for participants to add their own materials as well, to customize the resource so that it was useful for them.

Because participants represented a variety of backgrounds and experience levels, we knew their reference needs might vary. In addition to the resource manual, participants were allowed to select materials through an online bookstore that would meet their own individual needs relating to the integration of technology and instruction. The amount of resources available to each participant was based on participation in the series, at a maximum of $250 per participant.

Through the University's web site, a web presence for the seminars was created. Web Developers were contracted to build the template that was used as an interface for this project, making this important information available to educators worldwide. At Perkins Presentations, visitors can review the handouts for a particular session, the computerized presentation (if applicable), or the actual presentation itself. Each session was also preserved on compact disc and video cassette tape with a copy placed at each campus's library, so that anyone on campus could review the material without accessing the web site.

Session I encompassed Pre-Course Development. Participants were provided with checklists for starting a new course and continuing to present that course in subsequent semesters. Sample letters and other relevant items were also provided. Session II was entitled Converting A Traditional Course To Online Part I. This session reviewed the theory or "thinking" part of converting a traditional face-to-face course to an online version. Participants brought in a syllabus for one of their own courses and completed some of the exercises necessary to complete this process. Session III, Converting A Traditional Course To Online Part II, dealt with the "buttonology" of converting a course. This session worked extensively with Blackboard, the university's platform for online learning. Its goal was to take participants through the process, step by step, of loading lectures, tests, announcements, etc. The subject for Session IV was Building Assessments. Participants discussed matters related to online testing and evaluation, including minimizing academic misconduct and importing test pools into the university platform. Course Facilitation was the topic for Session V. Various electronic methods for increasing student communication and interaction were discussed. Session VI, Using Blackboard as a Supplement, was chosen as the final workshop. Participants were able to draw on the technical information presented in the first five workshops and see how to use it in a more limited, supplemental fashion.

The Results

Participants evaluated each session individually as well as the program as a whole. Of the 48 respondents who completed the evaluation process, 76% had 5 or more years of traditional teaching experience; 17% had taught for 1 to 2 years and 7% had 3 to 5 years experience. Twenty-three of the participants (59%) had no prior online teaching experience and 36% had no experience using technology as a supplemental tool in a traditional classroom setting. The majority of the participants were from the main campus (60.4%) and 45.8% attended all six sessions.

Although 7% of the participants surveyed were undecided, the remaining participants indicated a willingness to supplement their traditional courses with technology (specifically Blackboard) and 92% expressed an increased likelihood of developing an online course in the future. The resource manuals as well as the web site were found to be extremely useful tools as well as the opportunity to interact with other professionals who had already designed online courses and supplemental materials. Forty percent of the participants indicated a preference for more "hands-on" type sessions with specific examples of ways to incorporate the technology into the classroom. According to one participant, " . . . I would actually like to sit down in a lab and design an online class or shell with assistance from the gurus. . ."

The ratings from the individual sessions mirrored the overall program ratings. Those sessions that incorporated more technological skill were more highly rated than those dealing with other areas. This finding is in keeping with the high percentage of participants who rated their skill at the level of novice. More experienced participants rated the sessions highly as well; however, their concerns were more related to issues of evaluation and assessment of current courses and conversion of traditional courses.

Conclusions

Given these findings, future plans include the development of workshops for both novice and experienced individuals. These will include more opportunities for "hands-on" experience as well as opportunities to discuss issues related to specific disciplines. The overall concept is one of an online institute in which individuals would be able to choose from a variety of offerings based upon their specific needs.

THE ISSUES FACED BY TRADITIONAL CLASSROOM TEACHING STAFF WHEN CONVERTING COURSES FROM FACE TO FACE TO ONLINE.

Jenny Newby-Fraser, Manager, Centre for Learning Technologies, Waikato Institute of Technology, Hamilton, New Zealand jenny.newbyfraser@wintec.ac.nz

Introduction

Wintec, a traditional face to face teaching institution, identified a need to move into online teaching (OT) and learning. Wintec teaching staff have a lot on their plate and converting some of their courses to contain an online component causes anxiety for many. The Centre for Learning Technologies (CLT) was established to support the institute's OT initiative. Its role is to work with teaching staff, (the content experts and content developers), and support them with project management, instructional design, curriculum development, WebCT technical and design issues.

As Rogers (1983) predicts, Wintec has staff at the five stages of motivation: Innovators, Early Adopters, Early Majority, Late Majority and Laggards. Approximately 70% of Wintec staff are in the Early and Late Majority categories and these cohorts are more conservative and averse to risk. Most staff are in the Early Majority category however and all need support, reassurance, motivation and guidance (Newby-Fraser, 2000). There are many issues associated with the introduction of OT. A previous evaluation by the author found human concerns, rather than technical concerns, came through strongly. Boettcher and Conrad (1999) state that, *"Change is difficult. It takes time, energy, resources and altered attitudes"* (p.12). This paper concerns itself with how such changes affect teaching staff.

Methods

The study was both qualitative and quantitative and involved 17 staff completing questionnaires incorporating the following 12 statements:

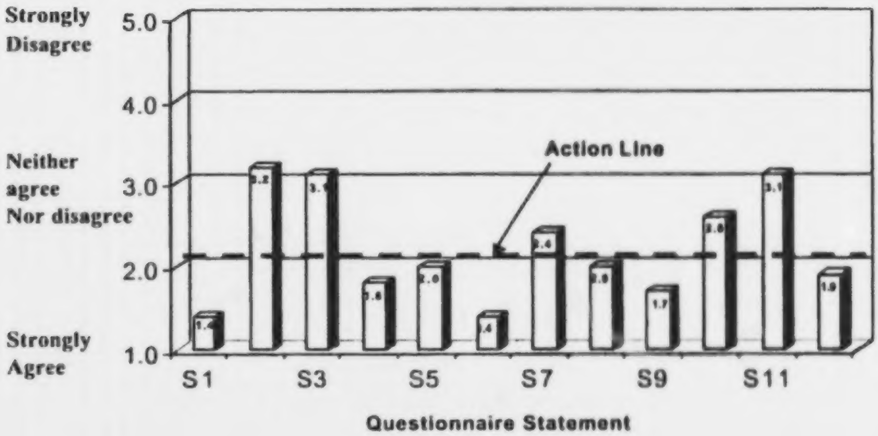
S1: I was given sufficient CLT support in the development of my online course.
S2: I was given sufficient time release to develop my online course.
S3: I did sufficient professional development to make me feel comfortable prior to starting OT course development.
S4: Converting my course to online has made me review my course content.
S5: Converting my course to online has made me review the content of my assessments.
S6: Establishing a sense of community within my online course is essential.
S7: Compared to face to face teaching my online teaching has been as effective.
S8: Taken overall I am satisfied with the online component of my course.
S9: I get a buzz from teaching online.
S10: Converting my course to online has affected my face to face teaching practice.
S11: After converting my course to online but before I actually taught it I felt comfortable about online teaching.
S12: After teaching my course online I felt comfortable about online teaching.

Each statement had a Likert scale (Strongly agree = 1 to Strongly disagree = 5) and provision for open comment and suggestions. Verification of the results of the questionnaire was obtained by asking a volunteer focus group outside the questionnaire group. Likert scales were analysed for their mean, median and mode. Those statements scoring above a mean of 2.0 were examined for future action.

Results

Of the 12 Statements regarding staff concerns during conversion of their courses to OT, the means of five statements (S2, S3, S7, S10, and S11) were above the 2.0 "Action Line" (Fig. 1).

Figure 1. Mean Likert Values of Evaluation Statements



In Statements 2 (release time) and 3 (professional development), a good proportion of staff did not agree. In Statement 7 (online teaching is as effective as FTF), although the mean was 2.4, the mode and median were both 2 and this indicates that scores were skewed below the mean. The mean may therefore be a slight overestimate of the average results. In Statement 10 (online has affected FTF), although the mean was 2.6, the mode and median were both 2 and indicates that scores were skewed below the mean. There appears to be a strong dichotomy of opinion among the staff on this statement as there is a gap between the majority of staff answers and the four staff who strongly disagreed. In Statement 11 (comfort prior to teaching online), both mean and median were 3.0 and the mode 2. This indicates that scores were fairly evenly distributed around the mean and the mean is a fair estimate of the average result.

Confirmatory Interviews

The three interviewees agreed in general with the questionnaire scores and comments. The only factor stressed more heavily by interviewees was the importance of course ownership.

Discussion

For change in delivery to be successful, the majority of staff must see some benefit from participating in a mixed mode delivery initiative, e.g. Release-time, technical and pedagogical support, professional development, promotion opportunities. (Newby-Fraser 2000).

Greater release time (a precious commodity) is a clear staff need. I agree with Oblinger (1999) that, a mixed mode initiative cannot be successful unless a substantial portion of mainstream staff buy into it. Without release time, they won't buy. Ideally, staff should have release time from some of their regular teaching commitments to work on their course redevelopment, or development, on negotiated allocated days in the CLT.

Then there is the issue regarding the time allocated for OT, although perhaps this is only an issue the first time it is taught, and perhaps it is highlighted if the course design is inappropriate.

"I did not realize the amount of time I would need, never having done this before. I did not allow time to learn about "how to manage" the course."

Staff do need to learn new skills to facilitate online teaching (Vardi & Bunker 2001).

Both the scores and comments in Statement 4 confirmed that much of the release time staff have been given for OT development is spent changing their content and updating their material. Although much of this work needs to be done for their FTF teaching, for a number of reasons it often does not get done. Staff comment on how much easier it is to "fly by the seat of your pants" in a FTF class than it is online. In the online world materials need to be prepared well beforehand. It is important for staff, and management, who

BEST COPY AVAILABLE

are planning on course delivery redevelopment to know that staff need time to do this. It will be interesting to see if these figures change over time as staff become more familiar with OT. One of the interviewees highlighted the formative assessment tools (eg. quizzes, matching exercises, cloze procedure) that are used increasingly by staff who teach the lower level courses. She commented, *"Self-marking more immediate."*

The results also clearly indicate that staff need more professional development in the online world. Successful online teaching and learning depends on teachers acquiring new competencies. Staff need to learn how to facilitate online, to learn new competencies in designing effective online learning environments and facilitating online (Palloff & Pratt, 2001) however many of the respondents would agree that many of these competencies are the same no matter what the mode of teaching.

The strategies and techniques staff use in their FTF teaching remain very relevant. *"Good teaching, is good teaching."* (Ragan, 1998,) Staff were asked to list the qualities of an effective online teacher and they provided a very long and comprehensive list. They believe that the requirements of an effective online teacher are actually a subset of effective and competent FTF teachers (Newby-Fraser, 2000). As one staff member commented, they were,

"*Willing to try a variety of delivery methods based on recognized teaching theories and practices.*"

Staff need to learn how to communicate and facilitate online. Students too need to learn how to communicate online, however they can be guided, facilitated, supported into this through thoughtful course design and teaching. We are mindful that student satisfaction depends more on the quality and effectiveness of the instructor and the instruction than on the technology (Johnson, Aargon, Shaik, & Palma-Rivas, 2000). One staff member who hadn't done any professional development commented,*"I did not know what I did not know!"* I think staff need to experience being an online student themselves. For a reflective practitioner this is a very valuable experience to have.

The results show staff are aware of the importance of a sense of belonging among the students in their course. *"Fruitful learning experiences don't happen by chance"* (Kimball, 1995) cited in Murphy & Cifuentes (2001, p.297). To build an online community, groups must share who they are *"as people...to build that container of trust"* (Pallof & Pratt 1999, p.7). On a sense of community some staff commented,

"Essential for student interaction and discussion. This is time consuming but very important".

The staffs' perception of the effectiveness of their OT in comparison to their FTF teaching (Statement 7) scored a mean of 2.4. Wolfe (2001), a Wintec midwifery online teacher, commented on the *change of roles* for her with OT. In the FTF classroom she is often the most "active participant" and enjoyed the various roles "teacher, director, organiser, actress". Online she found her students often interacted with each other, expanded on ideas, shared online resources and sometimes almost excluded her! Becoming an online teacher for many has been quite a learning curve. This is well documented in the literature.

"The role of the instructor is still key but changed." (Harasim et al, 1999, p.9).

Overall, staff were happy with their OT efforts and some wanted to take their OT to greater heights:

"It has been challenging but has reinforced the basics, especially of planning, of good teaching practice. The feedback from students confirms this."

Most staff got a buzz from OT. Harasim *et al*. (1997) agrees and says teaching staff should be motivated sufficiently to start online conversions and satisfied when they are finished. I was very interested in knowing if teachers who enjoyed being in the FTF classroom with their students still felt that same excitement when working online with them. Generally from these results there seems to be an energy, excitement, and motivation related to teaching online, even when staff are unhappy about release time (not enough of this) and professional development opportunities (not enough of these). It appears therefore that staff who enjoy traditional FTF classroom teaching also enjoy working in the online classroom. It is the challenge and also the opportunity to extend themselves into doing something different.

In FTF teaching we get our "buzz" from being in the classroom among students. As two staff members put it,

"I just love it!"

"Definitely gives a sense of satisfaction. Ability to quickly change online notes."

Although the scores of Statement 10 indicated a dichotomy among staff opinion on whether OT affected their FTF teaching, based on qualitative comments alone, I perceived staff strongly agreed that it did.

"*I have found that having to change material for online has made me look ahead in my face to face teaching - look at the effect of what I do.*"

"Positive spin-offs for your teaching generally."

Many staff definitely felt anxious before delivering their OT course. This was expected because the majority of staff participating were "first-timers" in converting courses to OT. Perhaps more professional development would help alleviate some of this anxiety although anxiety levels related to teaching online dropped markedly after staff had actually taught online. This is in line with what many experienced OT teachers say about OT, and indeed I would say about FTF classroom teaching. After we have taught a course once we are much more comfortable. One staff-member encapsulated it nicely:
"It is always stressful trying something new."

The study confirmed that: human aspects are the main concerns of Wintec staff; release time and staff professional development need further attention; and with knowledge of the specific causes, apprehension in teaching staff can be minimised. Technology issues take a back seat. I agree with Epper and Bates, (2001,) *"Probably the most important finding from the study is that best practice institutions keep their focus on teaching and learning issues and not on the technology itself" (p.144).*

Single–click Interactive Java Programming Tutorials on the Web

Jan Newmarch, School of Network Computing
Monash University, Australia, jan.newmarch@infotech.monash.edu.au

Abstract: Teaching programming is often best done by running and demonstrating programs, both by instructor and student. Programming environments are often very complex, and may hinder understanding of a lesson that does not involve the environment. This paper describes how the environment can be hidden, so that program compilation/execution is reduced to a single–click from a Web page. Programs can be modified within a Web page and re–executed again with a single–click, improving prospects for experimentation and student–centred learning.

Introduction

One of the major features of the Web is the ability to follow links to a wide variety of content using a single–click. This feature has proved so desirable that ecommerce models built on "single–click purchases" have even been patented.

The Web has been used for conveying teaching materials, and there is a huge literature on the courseware available on the Web (previous WebNet or any other Web conferences such as Asia–Pacific Web have conference sections devoted to the use of the Web for education). A large amount of this literature is concerned with techniques and application of learning models for structuring the courseware so that single–click navigation is profitable. Some literature uses plugins of various kinds (such as ShockWave) to deliver certain effects judged to be of educational value.

Computer programs are represented statically, but can only be understood by dynamic execution. Teaching programming is often regarded as a laboratory subject due to the need to run and to experiment with programs. Courseware on the Web (as with other media) is unable to aid directly in this, and there is often a means of accessing complete working programs, either by cut–and–paste or by FTP downloads.

An experienced programmer will not have difficulties in copying and pasting example programmers into their favourite programming environment, and will put up with various arcanities such as the Java main() method in order to play with new concepts.

The novice on the other hand faces a large number of difficulties just in dealing with any programming environment

- how does the editor work?
- how are individual programs or projects of many programs dealt with?
- how are programs compiled and linked?
- how are programs run?

It is common for the first few weeks of any introductory course to concentrate of getting students familiar with their local environment (such as an IDE or Unix command line tools). Educational systems such as BlueJ for Java (Barnes, 2002) are often used to try to remove as many enviromental issues as possible to allow concentration on pedagogical issues only.

This paper reports on a project to aid in learning Java by offering single–click compilation and execution of programs displayed in Web pages. The programs are given in TextArea's within browsers so that they can be displayed and edited (for experimentation). A single–click then delivers these to a server where they are compiled and the class files returned to the browser to be run as WebStart applications (webstart, 2001). The editing environment is familiar to users from previous experience with forms, while the compile and execution environments are hidden.

Previous work

In (Newmarch, 1996) we reported on a scheme to allow C programs to be displayed in a browser, edited and then compiled and run back on the browser side. There are many security and trust issues involved in this:

- If the browser can edit and send a file to a server, then the server will not want to perform any potentially dangerous operations such as executing code from an external source. Certain operations such as compilation may be safe, but execution may not be
- If the browser receives code from a server, then it must trust the server before it should execute it
- Any messages between internet nodes can be tampered with, so should be signed if there are possibilities that hostile code may be introduced by a third party

In addition, there are many environmental issues. Simply, C code is usually compiled to code native to a particular processor, and is not portable between either processors or operating systems. This generally means that compilation and execution must be done on the same machine. This machine would either be the server (too risky) or client.

The scheme used in Newmarch did solve the problem, using proxy servers running on each browser machine. It used a security exploit on the servers that made them execute code locally rather than transmitting it. This was extremely complex to set up, required administrator access to student machines, and was fragile in use. The scheme was used successfully for a few years, and then broke due to an unknown cause and could never be made to work again.

During the period in which it was working, both I in my lectures and students in labs used the mechanisms extensively. One click live demonstrations of programs proved very effective, especially when they could be edited in place to show variations, re–executed with just another click.

Requirements of single–click execution

A program needs to be displayed in a browser or plugin called from the browser and executed locally. Intermediate steps may involve compilation to executable or intermediate code, and may or may not involve round trips to a server.

Local execution means that the program must be run on the same machine as the browser, preferably in the same execution environment as the browser. It should be possible to interact with a program using keyboard and mouse. These rule out a number of possible technical solutions such as remote execution or using a proxy running as a different user.

Local compilation and execution may be preferable for client–side security. However, the variety of possible compile and execution environments makes this infeasible for all but the most common interpreted environments. Programs in a language such as C, with a multiplicity of compilers, need a high degree of local customisation. Languages with platform independent intermediate forms such as Java and Emacs Lisp can be compiled on servers and delivered to local platforms for execution (once the location of the local interpreter is known).

Execution of all but the most trivial programs will require access to local resources, and this may be problematic for security reasons. For example, a Java applet cannot be used to demonstrate file I/O using the standard applet sandbox security model since file I/O is disallowed under this model. There are weaker forms of the sandbox model that can be used in recent versions of Java. This requires trust in the executing code, and this trust must be present for all other possible solutions.

WebStart

The Java Network Launching Protocol (JNLP) is designed as a way to download and run Java applications by clicking on a particular kind of URL. URL's with extension .jnlp are associated in a browser to a helper application webstart. A JNLP file contains information about jar files and any other files (such as appropriate version of the Java runtime) required to run the application. The helper checks local system resources and downloads any required classes or resources before starting the application.

JNLP allows a one–click method of downloading software and running it locally. It takes care of ensuring that dependencies are met and a suitable runtime is present. It will download just the minimum to ensure this.

It has a security model that restricts code to a sandbox model unless the code is signed, in which case it may be allowed to run with no restrictions. This is a very coarse–grained security model, with far less options than are allowed with the Java 2 security model. The options are not appropriate for Jini code, for example, which should often run in a "sandbox with networking". Nevertheless, the all–permissions model does allow trusted code to run and do interesting things locally.

Interactive Web programs

By combining the ideas from our earlier work with WebStart, we can get a one–click interactive environment for demonstrating Java programs. The "compile once, run anywhere" property of Java means that most of the complications of languages that compile to native code can be avoided. The one–click environment is built from the following components

- A TextArea is used to display a Java program within an HTML Form. This can be edited to demonstrate variations, or submitted as is
- Form submission calls a CGI script/servlet/etc on the server which attempts to compile the program
- Errors are reported back in text/plain format
- A correct compile results in generation of a signed jar file containing the compiled classes
- A JNLP file is returned to the browser, which needs to be configured to hand this to a WebStart helper
- The WebStart helper uses the JNLP to download any needed files from the server
- The program which originated from the browser is then run in the browser's environment, allowing full user interaction

Engineering aspects

Lifetime

The Java source files are extracted from the Form data, compiled and used to create a jar file. Essentially, this is an atomic action, and after creation of the jar file the source and class files are no longer needed.

A response can then be sent as a JNLP file back to the browser, which references the jar file. The browser will call WebStart which will fetch the jar file after checks on the local system. After this, the jar file is no longer required on the server.

Managing this bumps into the standard web problem of stateful access in a stateless system. The response of a JNLP document ends a request session from the browser, and the interaction between WebStart and the server is a separate session. The current implementation handles these issues in the following manner

The "atomic" operation of creating the Java source files, compiling them, building the jar file and deleting the source and class files is protected by a file lock

The jar file is given a unique name for each session, and this jar file is stored persistently in the file system

After some "reasonable" time it can be assumed that WebStart has fetched what it needs of the jar file, and it can be deleted. This is similar to a cookie "timing out" and releasing a resource on the server

Visibility

To illustrate a programming concept it may not be necessary to show a full program. A couple of classes, or perhaps just some methods of a class might be enough. The current implementation uses the class as minimum unit. That is, one or more classes can be shown in TextArea's for editing. This may not be enough to actually run a program, and additional classes may be needed.

These may be included in two ways

- as hidden fields within the Form
- as references to jar files held on the server

Non-GUI programs

WebStart makes the assumption that downloaded programs use a GUI interface. This is not in the specification, and is just ignored as an issue. The Sun implementation of WebStart just discards I/O involving System.{in,out,err}. Other possibilities might have been a flag within the specification to include this environmental possibility, or to have an equivalent of the Netscape "Java Console" to handle this form of I/O.

There are many situations where one might want to avoid this assumption

- A lesson on a basic topic such as Vector would not want the complication of GUI code
- Some versions of Java – the J2ME restricted environments – do not even have the AWT or Swing classes
- Lessons on the JDK1.4 new I/O classes may not want GUI code complicating things

Objects such as System.in are declared final and so cannot be reassigned directly. However, there are methods such as System.setIn(...) that can be used to reassign these objects. Using these methods, it is not too hard to build a "GUI wrapper" that consists of a Text or JText with I/O linked to System.{in,out,err} by pipelines. The wrapper can be used as the main controller from a hidden field so that it need not be visible to the student.

Results

I currently teach a subject "Distributed Programming using Java". The Web lecture notes for this subject are being modified to allow one-click execution of programs (after WebStart has been installed). A sample lecture is at http://jan.netcomp.monash.edu.au/distjava/socket/lecture.html

Using this, it is straightforward to demonstrate even multithreaded and network programs using clients and servers, and modify the code in place. The subject will next be taught in August, and usage of this will be monitored throughout the teaching period.

Conclusions and future work

A system is running and is being used to modify existing teaching material of the author. Some parts of the online Java Tutorial are also being modified (in private copies) to demonstrate that this system is not tied to a particular teaching style.

There has been substantial work done on a teaching environment called BlueJ. This is a standalone system at present. Investigations are being made into integrating BlueJ and WebStart technologies to allow Java courseware on the Web to be imported into the BlueJ teaching environment.

Building a Hybrid Learning Community

Submitted by Thanh Nguyen

As email, synchronous and asynchronous threaded discussion boards have increasingly become important communication tools for students and teachers, building a hybrid learning environment plays a critical role in enhancing student learning. "Hybrid" is the term commonly used nationwide to describe courses that combine face-to-face classroom with computer-based instruction. Activities in a hybrid course could be a mixture of Web-based and face-to-face discussions, or virtual classes where students could upload and share their works online before presenting theirs to others in the face-to-face learning environment. Also after their presentations, others could review their works for feedback. Because a hybrid learning environment allows students to have more time in giving their opinions, students could express their thinking and learning without being limited by their shyness or learning disabilities. For example, a near-blind student could take the time needed to read others' responses, or an English as a Second Language student could take time to understand other's writings.

Teaching with a hybrid format allow instructors not only having activities for usual face-to-face meetings, but also uploading a course syllabus, files, assignments, PowerPoint presentations with voice and sound recorded, streaming videos, posting grades and tracking student works. The instructors could make announcements or send messages to each or all students through the message board. Once class information was uploaded onto the class website, instructors would know for sure that students could get access to the information without worrying about student's losing their works or instructions. Using this hybrid format, students can take more responsibility in their own learning. For example, they can upload their assignments onto the course site, share their work with the class or with members of a work groups at their choice, or can search the web and email each other directly using clickable email aliases embedded in the course pages.

The threaded discussion forum allow instructors to check on students' knowledge through conversations exchanged on the forum or from topics covered through reading assignments. Best of all, the discussion forum allow students to share ideas with other students in class, extending the work during in-class discussions. Here is what students say:

- I enjoyed using the threaded discussion board for various reasons. It helped to create a thoughtful dialogue as each person carefully thinks over their answers. I enjoyed hearing from each of my classmates. My classmates writing often give me something to respond to in my writing. Sometimes I feel like it was kind of impersonal since I couldn't always connect the writing with the actual person in the room. Overall, however, I think it is a successful tool.

- I have really enjoyed having access to this online site where the class can find information, share ideas, contact our classmates etc. It is something new and I enjoy exploring its different features.
- I really like typing my responses and reading the comments of my classmates. First, I like that I don't have to do some extra journal before class. I like coming and applying what I read. It helps me see if I understood it after awhile and also serves as a refresher for the class discussion. I like reading everyone else's comments as well. They are written highly intelligently and sophisticated. I find I get more out of my classmates written and synthesized thoughts than if we just had an oral discussion. In an oral discussion, not many people talk and those that do always talk. It's nice to hear shy people's thoughts as well as boisterous ones, because they are all very important and have contributed significant insights to me.
- I think the threaded discussion board has worked fairly well -- it gives everyone in class the opportunity to express his/her opinion thoughtfully and everyone has a chance to be heard. Too often, one or two voices dominate class discussion but the online discussion eliminates that problem.
- I like this web-based environment as a tool for this class. It is convenient to get assignments online and respond to discussions online. As far as learning, I can't say that I've learned a completely new concept but it adds a new dimension to the course.

Technology Leadership Academy

The Technology Leadership Academy is a project funded by the U. S. Department of Education's *Preparing Tomorrow's Teachers to Use Technology* (PT3) Initiative. The mission of the Academy is to develop a collegial network for the infusion of technology into teacher preparation within the four-state area of Kansas, New Mexico, Oklahoma, and Texas. Academy partners include the higher education community, state agencies involved in teacher education, and the corporate sector. This presentation will showcase how the Academy has developed an online learning community for technology infusion and how faculty members can create this collaborative environment at their universities and in their regional areas to elevate faculty teaching and improve adult learning. Additionally, the Academy's online tutorials for faculty development will be highlighted.

The mission of the Technology Leadership Academy, a component of the Technology Leadership Institute, is to develop a learning community among teacher preparation programs. During the past three years it has grown from an abstract concept to an organization with around 450 members within the four-state area of Kansas, New Mexico, Oklahoma, and Texas. The Academy's membership throughout the world spans to 2,000 members. From the beginning, the goal was to build a collegial and collaborative organization to provide mutual support and sharing of resources in the challenging task of infusing technology into teacher preparation. The first organizational meeting, hosted by The University of Texas in January 2000, was attended by key officials from 85 universities and state educational agencies from the four states. Activities included: finalizing the Academy's organizational structure; establishing priorities; dividing into task groups (each concentrating on one aspect of the Academy's mission); nominating chairs of each Task Group (to serve on the Steering Committee and oversee the Task Group's functioning); and identifying a set of directives and recommendations for the Task Groups.

The Steering Committee, comprised of deans, faculty and technology directors, provides direction and oversight of the Academy's activities and meets several times a year to review progress and discuss future plans. There has been a shared responsibility in the development of the Academy, even though the distance across these institutions makes this task even more challenging (and yet so rewarding).

Each Task Group is chaired by a Steering Committee member and consists of volunteer faculty or staff from the member institutions and state educational agencies. Each Task Group is responsible for determining and coordinating its specific part of the Academy's functioning. Eight Task Groups emerged from the organizational meeting of the Academy. These included: Assessment and Planning, Academy Web Community, Consultants Database, Fall Institute, Policy and Leadership, Professional Development, Regional Conferences, and Technology Integration. Last year, the Academy formed a ninth committee, the Digital Equity Task Group, to ensure that the other eight Task Groups were addressing digital equity issues in their efforts.

The Academy facilitates an online tutorial process to provide on-going professional development opportunities. The Academy Web Community Task Group has developed a Faculty Mentor and Faculty Subject Area Mentor. These projects are unique resources that use a question and answer format to allow faculty members access to relevant online faculty technology professional development resources, models, and research. The Subject Area Mentor has four content area components: English-as-a-Second Language, Mathematics, Science, and Social Studies.

Academy members are represented on the Educational Technology Coordinating Council which developed the State of Texas Master Plan for Educational Technology 2000-2003. The mission of the ETCC is to ensure the cooperation and coordination of the state's efforts to implement education technology initiatives. The State of Texas Master Plan for Educational Technology is aimed at pre-service and in-service training in technology integration for teachers and librarians. The Master Plan includes eight goals and objectives which identify the organizational infrastructure and data requirements necessary to measure successful implementation. Included in the goal descriptions are definitions, levels of impact, lead agencies, participating agencies, objectives, limitations, and due dates. One of the most significant sections in the Master Plan recognizes 12 Recommendations which serve as an implementation plan for achieving statewide collaboration for educational technology.

Although competition within universities can be used in a positive manner, the focus of the Academy is to instill close, working relationships among and across institutions. The Fall Institute, the Academy's annual conference, is an activity used to accomplish this goal. Teams of 3-5 individuals from member institutions participate in a 3-day conference focused on infusing technology into teacher preparation programs. Academy members also participate in organizing Regional Conferences on member campuses to strengthen the face-to-face component of the continued attempted by the Academy to provide a structure that fosters community and resource sharing.

The Academy has devised a project to recognize outstanding faculty members who are effectively infusing technology into the curriculum. The purpose of the Consultants' Database is to develop a comprehensive listing of faculty with expertise in various areas who have agreed to be featured on the Academy website in a biweekly segment and to be part of a database of resources.

This session will be an interactive experience, whereby mutual benefit will exist between participants, between the participant and the presenter, and vice versa. The following objectives guide this session:

For participants to

1. Become familiar with the mission, goals and objectives, and components of the Technology Leadership Academy;
2. Participate in a discussion regarding issues involved in building an online learning community;
3. Learn about the process that the Academy took to develop this community (discuss benefits and challenges of certain strategies taken);
4. Contribute ideas on how the Academy can reach more faculty members.

Our overarching goal is for the participants to share ideas with the presenter on how to encourage more faculty members to become involved in the Academy and how to continue to meet our members' needs.

Abstract

Research suggests that education needs to embrace IT, use it to provide quality, flexible teaching and learning. In order to be competitive the organisational structures need to reflect the environment, this meansa change from the rigid, inflexible internal/stable structure. Findings suggest that, technological developments will change the role of the lecturer.

The expectations and learning styles of students and staff are increasingly diverse. Learning is regarded as a lifelong activity. Distance learning is becoming commonplace. Increasingly there is an emphasis on lifelong skills.

The solution is simple! Introduce technology, video conferencing, labs of PC's with powerful software. Significant investment has been made in technology within Education to enable students to use a very powerful computer to word process assignments and 'surf' the Net! Staff are little better, intrigued or disillusioned with video conferencing, seeing it as 'glossy' or at best futile in the context of learning delivery. This paper considers some of the issues raised and addressed by the development and implementation of our own in-house Virtual Learning Environment.

It is often said that we are entering or even part of the Information Age. This coming period could equally be called the Age of Learning: The sheer quantity of learning taking place in the world is already many times greater than in the past. For example, not very long ago, and in many parts of the world, young people would learn skills they could use in their work throughout life. Today, in industrial countries, most people are doing jobs that did not exist when they were born. The most important skill determining a person's life pattern has already become the ability to learn new skills, to take in new concepts, to assess new situations, to deal with the unexpected. The competitive ability is the ability to learn. Information technology, from television to computers, affords an opportunity to enhance the learning experience.

Children have seized this opportunity, they have entered a passionate and enduring love affair with the computer. What they do with computers is as varied as their activities. The greatest amount of time is devoted to playing games, with the result that names like Nintendo™ have become household words. They use computers to write, draw, to communicate, to obtain information. Some use computers as a means to establish social ties with other cultures, while others use them to isolate themselves.

However with all the technology and the ability to access it where or what has changed, in terms of a teaching and learning environment. If a party of time travellers from an earlier century descended on us what would they see. If they consisted of surgeons and teachers. The surgeons, irrespective of their competence, might recognise that some operation was taken place, but there would have no idea of the environment, or the technology or of the strange devices and tools which the present day surgeon would be employing. The rituals of antisepsis and anaesthesia, and even the bright lights, would be utterly unfamiliar to them. The teachers would respond very differently. They might be puzzled by a few strange objects, and there will be some debate about standard techniques which had changed, but would be reasonably comfortable with what was being attempted and may even be able to take over the class. This is particularly true of some of the more traditional subjects.

Why, through a period when so much human activity has been revolutionised, have we not seen comparable change in the way we help people learn?

To date, classroom enhancements have replaced traditional apparatus rather than the process or didactic model of teaching:

⇒ The chalkboard replaced the slate;
⇒ the whiteboard replaced the chalkboard;
⇒ the OHP replaced the whiteboard;
⇒ software (Microsoft PowerPoint™ et al) replaced the OHP

Teachers/ lecturers felt comfortable with these changes as they were replacing the quill with the keyboard, the delivery mechanism, process and interface was essentially the same. So how to progress, there is a need to enable staff to consider the pedagogic implication of the on-line learning environment rather than the content.

The Internet potentially provides an opportunity to change all this.

According to Graziadei et al (1998), in order to implement and sustain remote, distance based computer mediated courses with a high probability of success, the following should be considered as the critical areas:

- enhancing/extending autonomous learning and productivity in the face-to-face traditional classroom setting
- creating a Web-presence with easy access to 'basic' information about online courses and interactive learning materials
- discovering/developing tools and standards to support new learning environments
- advancing our understanding of the virtual and distance university
- increasing community/off-campus access to the teaching-learning community
- providing evidence of the viability of these concepts

Staff are currently being asked to develop material for on-line delivery. This is an anathema to them. Not because of any motive other than competence in the pedagogy, technology environment etc. They generally teach the way in which they have been taught. As tutors they feel in control of this environment of physically teaching students, they are 'happy' with the quality and control and standard of the 'interface'. To introduce another medium is quite threatening and may well affect the quality of the experience.

If I could elaborate. I personally feel that something such as video conferencing (VC) is not as successful as perhaps it ought to be due to the 'tablet looking for something to cure..' syndrome. Have we developed a real use for VC? I would suggest not, so we create environments where VC can be used. This is surely not the thing to do. From my own experience setting up e/mail in schools for pen pal use failed miserably. This was because I introduced e/mail and then something to do on it...However I rapidly learnt a lesson. In a number of other schools I introduced the staff to e/mail and provided an opportunity for them to exchange pictures/ letters/ curriculum ideas and projects. These were via e/mail and more traditional means of communication. These teachers then developed local, regional, national and international databases and information exchange systems, the important fact being that *they* exchanged, *they* decided, *they* owned, developed and delivered. I provided and enabled a platform for them. The issues are about how teaching and learning are perceived within the organisation.

However we must maintain quality within our content and delivery. According to the literature, quality is concerned with meeting a defined specification(s). Clearly then, for learning to be considered as quality learning, it must also meet prescribed and accepted criteria. Nightingale and O'Neil (1994: p. 54), suggest that the indicators of high quality learning having taken place are:-

- being able to discover knowledge for oneself
- long term retention of knowledge (implying that there is understanding)
- being able to perceive relations between old and new knowledge

- being able to create new knowledge
- being able to apply knowledge to solving problems
- being able to communicate one's knowledge to others
- wanting to know more

But, they add the caveat that it is only possible to achieve this specification where certain pre-requisites for quality in learning are in existence:-

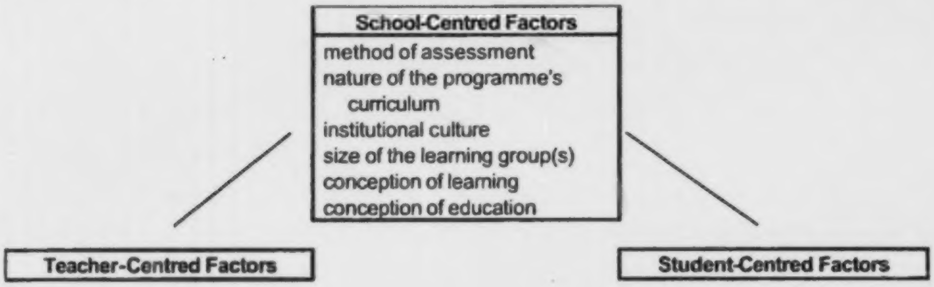
- the learner is ready to meet the demands of the learning task(s)
- there is a reason for learning (acceptable reason, to the student)
- the learner is active during learning
- adequate support is provided by the environment in which that learning occurs

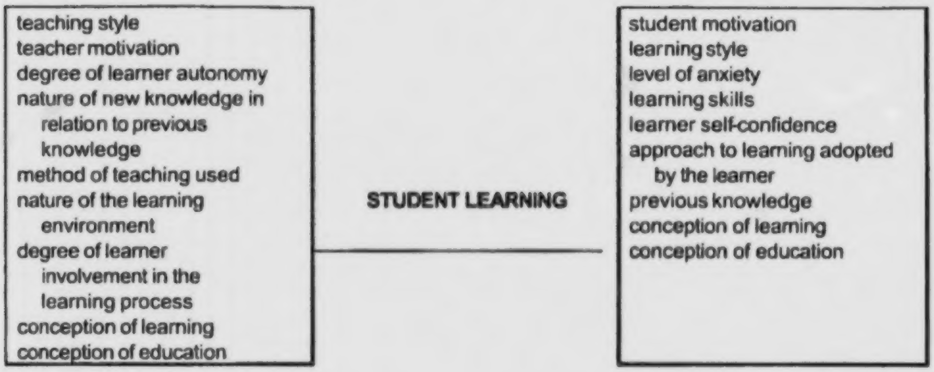
The adoption and implementation of such a model by staff in developing for an on-line delivery platform or for an on-line supported delivery platform will require a greater understanding of both the learning process itself, and also the most appropriate means to facilitate that process (O'Donoghue et al, 2001). This understanding is a pre-requisite for effective course design. But, I would suggest that at present, part of the problem is the differing conceptions held by academic staff as to exactly what; a) learning is, and b) what on-line facilitated learning is. But perhaps more importantly, future developments in course design, structure and delivery will continue to be at best misguided, and at worst potentially damaging to the quality of the learning experiences that are offered.

The challenge is to develop a curriculum which can emphasise interconnections between learning pathways, the practical application of knowledge in a variety of contexts and flexible relationships between core and specialist knowledge. It must be based on sound pedagogy. The focus on tutors is not on the training but on the facilitation of central processes of learning which too often is interpreted as something which is transmitted to people rather than an activity for which they themselves have responsibility. The teachers of tomorrow must have some involvement, experience and opinion of 'student-centred learning', 'flexible learning', 'open learning', 'active learning', 'on-line learning' etc.

Effective learning within this environment is:-

1) a function of the interaction between, *and* the interdependence of, 3 groups of factors
2) and a cause of that interaction





teaching style
teacher motivation
degree of learner autonomy
nature of new knowledge in relation to previous knowledge
method of teaching used
nature of the learning environment
degree of learner involvement in the learning process
conception of learning
conception of education
STUDENT LEARNING
student motivation
learning style
level of anxiety
learning skills
learner self-confidence
approach to learning adopted by the learner
previous knowledge
conception of learning
conception of education

Robotham, 1996

The approach of the tutors in allowing cross fertilisation and conceptual development of the student and tutor and technology must be fostered. It must allow various "partnerships" into which students will enter. Successful learning depends on success in establishing and developing such partnerships - with tutors and with collaborators.

However, such an attitude is not free of complication. It may be argued that one important goal of formal education is to cultivate a capacity to learn independently; in a sense to find some release from learning - as - partnership. Now, claims of this sort introduce an element of tension: we wish to develop partnerships for purposes of socially mediated learning, but we also wish to cultivate in the learner a certain autonomy. Tension of aims need not imply conflict of aims. Indeed, far from being in conflict there may be necessary developmental relationships between socially organised cognitive functioning and that which is 'private' or autonomous to the individual (Vygotsky, 1978). Nevertheless, at a practical level of formulating strategies for teaching, there does remain a tension to be handled. Thus, in practice, one thing teachers must surely consider is how they should manage the learning process in terms of a balance of emphasis between pupil autonomy and interpersonal exchange.

Curriculum and Educational Technology Dept.
University of Minho
Portugal
lia@iep.uminho.pt & eblanco@iep.uminho.pt

Abstract: In the context of a research-development study in progress, a website prototype was created (dynamic, interactive and multimedia data base) with the purpose of providing support to any subject-matter in teaching and learning at university. The aim is to make classes more flexible in the terms of space and time, providing a classroom virtual environment, based on "good pedagogical practices" of sharing and cooperative construction of knowledge. The model is briefly presented and the interface to be used by students is discussed.

Introduction

The new technologies of information and communication, and more specifically the Internet, have radically transformed the ways in which information is accessed and produced, as well as the scale of its diffusion. At the same time, forms of communication have changed, too. Universities, as generators of knowledge and agents of human resources development, are not dissociated from these phenomena and play a determining role within them. Both society and available knowledge are experiencing change and, consequently, workplaces demand flexible professionals with autonomous learning skills, ability to adapt and a cooperative enterprising capacity. In this context, the university needs to reflect upon the kind of education and the forms of learning it provides. Thus, we believe it has to undertake some changes in its pedagogical practices. One of these changes includes the effective use of the web as a didactic device for teaching activities. This implies not only transposing study material into the web, but also, and above all, creating and developing environments which aid methodologies and strategies so as to improve meaningful learning. We are not dealing with the issue of long-distance teaching but rather with the reconceptualisation of formal education through the use of technology at hand and its potential for communication and distribution. In fact, it is precisely due to this technology that we have witnessed a steadily increasing convergence between the two forms of teaching, which tend to complement each other both in education and training.

Intention and Objectives

The context of this project is a research-development study in progress, whose primary objective is to discuss and understand the process of conceiving and implementing a device for education/training. This objective distinguishes the project from other similar undertakings, which may concurrently occur over time. The purpose it to provide a working tool which will allow an essentially pedagogical and didactic reflection on the use of this technology in this context, in addition to a reflection on the technical, administrative and logistic aspects of the prototype.

A website was designed, aimed at providing support for any subject-matter related to learning at university. This prototype is to be used outside the classroom and/or in the classroom and provides support, both as a model and an example, for the subject of Educational Technology (3rd year of training for prospective secondary school teachers), which is taught in a laboratory regime, with special emphasis placed on project methodology and portfolio assessment.

The purpose of the website is to make attended classes more flexible, in terms of time and space management, by creating a virtual environment based on "good pedagogical practices" which can be translated into the notion of community (group, the feeling of belonging), sharing and the cooperative construction of knowledge. Flexibility will allow students to possess greater autonomy in their learning process because, during their training period, they have access to an interactive reference online regarding the subject and may use it in accordance with their personal characteristics (learning styles and pace).

More concrete objectives include the way in which access to relevant information is facilitated, making thematic communication more dynamic (students-students and students-teachers), promoting the development of information literacy skills, and simplifying some of the teacher's administrative and organizational tasks, thus contributing to improved quality in learning.

The Process of Creating the Device

The process of creating the device was undertaken in three phases: conception, development and implementation (analysis and assessment are currently under way).

The conception phase started with a literature review on the subject and a search on the web for related undertakings. From the analysis of available platforms (paid or gratuitous) for "virtual lessons", we concluded that they were either too complex for what was required (although some were extremely interesting) or excessively directed towards distance-learning. However, we found various specific undertakings which closely matched our intentions. We proceeded with some preliminary research on the existence of sites possessing these features, at Portuguese state universities, for the teaching of the subject under study (Educational Technology or other related subjects) (Oliveira & Blanco, 2001).

We then made decisions about specific objectives, the contents to be made available and the formats to use, the approach to communication/aesthetics, and the types of communication and interaction. The idea of "good pedagogical practices" previously mentioned was turned into a metaphor inspired by the categories of narratives (since Man is a consumer/producer of stories): elaboration of a story (i.e. construction of knowledge) in a specific dimension of time and space, by someone who makes something, using the resources required to meet common objectives and depending on some conditioning factors (Laurel, 1991, Depover et al, 1998). The communication/aesthetic options were as minimalist as possible, respecting the criteria of simplicity, easy use, clarity, consistency and induced credibility. The architecture of the final information was managed by resorting to the "post-it" technique (Boling & Frick, 1997) and the result is presented in the following flowchart (Fig.1).

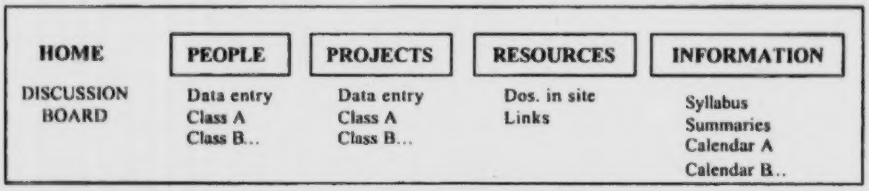

Figure 1 - Flowchart of the student interface.

The development phase - the technical execution of the site itself - counted on the collaboration of professionals from the areas of Systems Engineering and Communication Design (programming and surface structure). After elementary testing and site installment, we undertook usability tests not referred to at length here, which were fundamentally based on the analysis of "think aloud" individual protocols registered on video (Schriver, 1997), involving five participants representative of the intended users (Nielsen & Landauer, 1993, Reeves & Carter, 2001). Some changes were made as a result of these tests.

The website was implemented for a semester (2002) and was used by approximately seventy students from teaching degrees (languages and science). At present, we are analysing opinions gathered from these users (through questionnaires and interviews) and we expect to make the results available soon, especially those relating to the pedagogical interest of using the model in the given situation.

As for the system, the site has two interfaces: the student interface, that is, the shared environment (students and teacher) and the administrator interface (teacher) for updating and managing the information on the site. To make this possible, the online content is dynamic and is fed by an information system created by Microsoft Access (using Dreamweaver, Ultradev, HTML, ASP and Java Script). We are, therefore, dealing with a data base whose interfaces allow data uploading without authorized access to the server. We consider this aspect to be important for real interactivity at the level of both interfaces, so that the platform is not reduced to unidirectional communication (teacher-students) and directive discourse. Access to any of the interfaces requires login and a password.

The student interface is made up of five sections: Home, People, Projects, Resources and Information. These sections aim to reflect the adopted metaphor.

The Home section (Fig.2), presented as the site map (deeper information is accessed after a maximum of three clicks, due to the use of pop-down menus) proposes a type of simplified forum - a discussion board. A statement is under discussion (weekly suggested by the teacher) and the comments introduced are automatically inserted using a click (bypassing identification). These comments may be used to start a discussion at the beginning of a class. The principles underlying this option are reflectivity and voluntary participation. Thus, the Home is supposed to generate interactivity and participation.

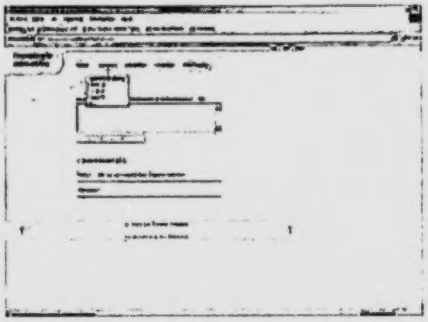

Figure 2 - Home and navigation menu.

The People section allows four entries: data entry and three classes.

In the data entry, students will find a form where they fill in personal data (photography included) which become available on a personal page made accessible via the course page. The teacher is part of the page since she/he integrates the group/community, although she/he obviously has different objectives from those of the students.

The Project section also allows four entries: data entry and three courses.

The data entry is also a form where students are asked to fill in synopses of the work projects in which they are involved. Their names (nicknames identifying them in the group) are connected with their personal page.

The Resources section allows two entries: resources on the site and external resources. The latter are traditional *links* of interest, which are progressively updated by students' contributions (the *links* are inserted by the teacher). At present, these are grouped as national and international.

The resources on the site are grouped according to the type of document: written texts (.doc), powerpoint presentations (.ppt), video extracts (.mpeg), still pictures (.jpg and .gif) and exercises (various formats). At present, these are presented on run-on pages (with *links* for the top of the screen and for the category) since it is difficult to predict the number of documents which can be inserted.

Various reference texts were made available, also powerpoint versions of some of them, assessment grids for projects to be undertaken as well as for various types of performance (student participation, teacher's activity), autonomous presentations in powerpoint, video extracts of documents seen in class, a set of images and a few exercises on computing tools. This possibility of insertion and the availability of multimedia documents constitutes an inevitable requirement due to the obvious advantages, for the process of learning, of using diverse symbolic systems to represent information (Depover et al, 1998).

All the documents are posted on a new window on the *browser* so that they can be seen immediately and may be recorded at the source of application.

The links to other sites use the same process of posting a new window on the *browser*, avoiding, on the one hand, an involuntary exit from this site (due to URL change) and, on the other, preserving their authorship (one of the many reasons why frames are not used).

The Information section summarizes institutional and administrative aspects: the formal course syllabus, summaries and calendar (for each course).

The syllabus page occupies one screen (containing a summary of it) and one can *download* from the respective file (.doc) as well as from a specific file concerning assessment norms, criteria and methods.

The Summary page is similar and allows one to download from the respective file.

The Calendar, as the name indicates, schedules the activities over the time-period estimated for attendance of the course. It is divided into months and days (on a run-on page) and presents a guiding summary for the activities to be developed.

As for possible forms of communication, apart from the initial discussion board which can be used in an asynchronous or synchronous manner, priority is given to the use of electronic mail. All the members of the class-community introduce their electronic mail address on their personal pages, which then becomes available for communication from this interface.

BEST COPY AVAILABLE

Electronic mail, as we know, allows private communication from one person to another but also from one to various people (e.g. mailing lists). It also allows one to send attached files in various formats. On the other hand, e-mail applications allow one to establish rules for message reception and dispatch (e.g. various filters) as well as to file, register and confirm reception. Thus, we believe that this mode of communication is the most suitable in this kind of situation, ensuring the privacy, speed and general efficiency required in the exchange of messages. Furthermore, it is via electronic mail that the transmission of assessment results takes place (formative and summative) both by the teacher and the students, through the use of selective mailing lists (individual, small group or course groups). This option is based on the fact that we consider evaluation, in any of its forms, to be a context-sensitive process which concerns the people involved and that, therefore, a certain degree of discretion and privacy must be ensured. This, in fact, occurs in the traditional academic context of publicizing results (posting marksheets). It is our belief that using electronic mail for this purpose over the learning period contributes to higher degrees of personalization, transparency and fairness in the assessment process.

Final remarks

No technology can be educational on its own. To understand this, you need only to use it (Jacquinot-Delaunay, 2001). The conception, development, implementation and evaluation of educational and training devices for the web necessarily demands deep reflection and discussion, not only regarding the computer software and communication aspects of operating those devices, but also and above all, concerning the pedagogical, didactic and curricular purposes and intentions which support them. With this text, we hope to contribute to this discussion and promote the transdisciplinary approach that this medium of communication requires.

WHAT ARE FACULTY'S THOUGHTS ON ASYNCRONOUS TEACHING? A CASE STUDY OF ONE COMMUNITY COLLEGE IN UPSTATE, NEW YORK.

Carol Oliver, MA
The Graduate School, The City University of New York
Environmental Psychology, Sub-Program in Psychology
New York, New York, USA
oliverc126@aol.com

Abstract - This research paper critically looks at professors' everyday work experiences teaching courses online, their work responsibilities as faculty within the larger university system and the issues that affect these faculty members. The paper illustrates how their experiences with asynchronous teaching have an affect on their professional and personal work experiences. The methods used for this study primarily involved qualitative research design and some quantitative analyses. Surveys and one-on-one interviewing were used for the collection of data. This paper is only a preliminary introduction to some of the data analyzed from interviews conducted with faculty.[1]

Introduction

The academic profession operates as a mentoring-training ground for professions, which include, doctors, lawyers, architects, engineers, and representatives of other advanced crafts or non-professional training (Clark, 1987). The academic profession involves varying dimensions of academic work, such as teaching, research, mentoring, evaluation of students' work, supervision and evaluation of dissertation work, administration and public policy work (Cahn, 1994; Clark, 1987; Markie, 1994; McKeachie, 1994). The question "*what do academics do*" is difficult to answer because it varies by discipline, institution, professional seniority, teaching styles and by personality traits, like temperament. The work of the professor involves teaching, mentoring, administration, and research, but these tasks vary greatly by person, institution, and seniority. Research and publishing serve as the primary basis for prestige in many disciplines and in the profession as a whole, and it is bound to play a substantial role in major universities (Clark, 1987, p.70). In addition, professors spread themselves beyond these two major tasks; some formally counsel students, some work in administration, some are heads of departments and others are active members in committees where they can vote on university policies and procedures (Cahn, 1994; Clark, 1987; McKeachie, 1994). Despite this range of activities, the workload of academics is usually defined by "teaching load" (Clark, 1987). In some cases, the workload may include supervision of students (both in the professor's research and in activities such as mentoring, studio work, dissertation work etc.) but teaching remains the institutional obligation for which hours can be specified. In graduate schools dissertation supervision is also considered part of the faculty workload and "research load" (for which one can get "released time" from teaching) is often assessed as a formal duty that is required for retention and promotion.

A review of the literature on the academic profession looks at "workload" in terms of "productivity,"(Green & Gilbert, 1995; Massy & Wilger, 1995; Robinson, 1997; Wulf, 1995). With the evolving use of information technology in academia, the work of professors is being measured by how much is produced within a specified time. Since information technology is allowing professors to do their work, including teaching, at a distance, the question of productivity has taken on new dimensions and in some learning institutions has become a concern. With email, distance learning, Internet technologies and fax, the method of delivering "*teaching*" or "*what professors will be doing*," will change as information technologies change the environment of professors' "work" and their access to students. While the research on distance learning continues to grow many programs and universities are continuing to develop this medium to 'deliver' educational courses (Blumenstyk, 1997; Curtis , 2001; Frenette, L. 1997; Jaffe, 1998; Jellinek, 1988; Luke, 1997; Maurizio, 1997; Margolis, 1998; Noble, 1997; Novek, 1998;).

---

[1] *The data for this paper is part of a larger data set that is currently being analyzed by the author for the completion of the dissertation.*

Technological advances in education are still met with skepticism by both educators and higher education administrators and teacher unions, (as reviewed in PSCcuny Clarion, 2000 Vol 29(6):5 -article entitled *"CUNY is not ready for distance learning"*). However, some academics and higher education administrators feel that distance education is a wonderful new teaching tool for learning because it offers flexibility of time and space and students can have access to professors by email and other online methods. In addition, distance learning education, can be attractive to the non-traditional learner (Ben-Jacob, et al., 2000). According to the article, *The Learning Environment of the 21st Century (Ben-Jacob. et al, 2000),* "the typical 21st century student will be an adult learner who is mature, more likely to be financially secure and more serious academically than today's student. A great number of these students will be employed full time and will pursue further education as a requirement of employment or for career advancement" (Ben-Jacob et al., 2000, p 8.). Distance learning will capture the interests of these different types of students because it provides flexible arrangements responsive to their time constraints (Ben-Jacob.et al, 2000, Berg, 2000). Conversely, some faculty members feel that distance learning is not "*a real education*" because students need to have face-to-face contact with educators. They view the online courses as inferior to the traditional classroom lecture, because they assume that distance courses cannot be rigorous enough to be academic (Ben-Jacob, et al., 2000). Faculty are concerned with *workplace* issues, such as the time that they spend designing their traditional courses online and how they will be compensated for the time they spend preparing a course. They are concerned with issues regarding evaluation for tenure and being retrenched by these new methods of teaching along with issues like publishing online, proprietary work and mentoring. Other ethical issues, such as universities becoming diploma mills, have become major concerns in the academic community ("An on-line experience," 1995; Curtis, 2001; Guernsey, 1997; Novek, 1996; Robinson, 1997; Young, 1997).

Currently, distance learning technologies are being used by professors as another teaching tool and not as a replacement to their practice of teaching. Questions of how professors use distance learning technologies in their work, if in fact, these technologies alter their teaching practices, and how teaching online may differ from teaching in the classroom, are important in looking at the profession in the context of professors' work lives when they use information technology. While some empirical studies on these questions have been done, studies have not looked at the teaching strategies that professors use when teaching online, nor has further consideration been given to issues of the professors' work environment. This research will examine these issues and will critically evaluate all aspects of the work lives of faculty that teach in online learning environments.

The Study

This paper is a result of one-on-one interviews that were done with faculty from a community college in Upstate New York. The faculty members at this community college were interviewed on issues relating to their online teaching *work* and *personal space issues* when teaching at a distance. This research was based on a larger data set, where 299 surveys where sent to faculty's homes asking about their experiences with computers and questions about online teaching. From the 299 surveys sent, 112 responded and 20 faculty members returned a postage-paid postcard that was attached to the survey, indicating that they would participate in the one-on-one personal interviews. The faculty members were contacted by email and given two weeks to respond to a date and time for the interview. Seventeen out of 20 professors responded and were interviewed. The interviews were taped and transcribed. The preliminary results that follow come from the interview data.

Preliminary Findings

The following is a grouping of preliminary findings that are currently being further analyzed.

What faculty favored about asynchronous teaching:

- Faculty members (n=17), in general were happy with the work they were doing using distance learning technology to teach. They enjoyed teaching online and felt that they had close-knit relationships with their students.
- Faculty expressed that they knew their students far better than they knew their face-to-face students. They had a stronger one-on-one relationship with their students because of the increased interaction they had with them online.
- Faculty stated that this was due to the more time they were spending evaluating individual student's work. They had to answer enormous amounts of email and discussion questions with each individual student.
- Despite the fact that the literature, and many non-distance learning teachers say that they do not teach online because they need the face-to-face interaction, these teachers felt that they knew their students far better than their traditional classroom students. They felt a special bond with the students and there was a *special* "virtual" communication that happened online between the student and the instructor.
- Faculty stated that students who took online courses were more reflective with their answers and homework assignments. Their writing was far better and they took more time to give well, researched answers.

What faculty concerns are regarding asynchronous teaching:

- All 17-faculty members stated that the number of students enrolled in their classes was *too* many. Student enrollment for an online class was the same as in a face-to-face class in this community college. For example, if a psychology class has a 30-student enrollment, then the department expected that the online class should have the same number of enrollments as well. All faculty (n=17) expressed that if enrollment was capped at an average of 15-20 students, it would be more manageable and less time consuming. Currently the community college has about 30-35 students enrolled in online classes at the time of registration, by the first weeks of class students enrollment drop to approximately 20 -25 students. *Faculty stated that the number of students made a major difference in the amount of hours they spent online!*
- One faculty member compared the amount of time and work in an online class with the classroom in a ratio of 4:1. The instructor said, *"For every hour I spend in the classroom, I spend four hours online."*
- Three faculty members reported ergonomic issues e.g. carpal tunnel syndrome; back pain; neck pain.
- Faculty stated that students who were not successful online were students who needed discipline, maturity and students who needed to be organized and structured in order to make their online experience rewarding and successful.
- Faulty reported that students, who dropped out during the first three weeks of class, needed more hands-on training as to the mechanical aspects of online course. They stated that they hope that the administration and the technology people could work together to give students more tutorial experiences.
- Two faculty members admitted that they were not happy with their dl experience because they were not utilizing the technical support adequately (by choice). These two faculty members reported that they were meeting with students online once or twice a week and giving them test --- they had no discussions with students online nor did they develop and online dialogue.
- Faculty stated that getting release time for teaching online or getting extra compensation for designing, preparing, or upgrading a course was optimal.
- Faculty stated that it was important to get more compensation because of the endless amounts of time they spent online evaluating student's work, participating in threaded discussions and answering large amounts of email messages.
- Two faculty members suggested that the university should be able to provide for the paid-Internet service at home, since they did all of their online teaching at home.

Abstract: Distance higher education is a rapidly growing and evolving phenomena, which is actively promoted in many countries. Despite this, there is a relatively small proportion of this effort devoted to the distance PhD: distance PhDs programs are relatively new and experiences are scarce, specific, and hard to generalize. How, then, can we approach the design of a distance PhD program? This is the focus of the paper. Issues addressed include the following:

What are the pedagogical motivators of distance PhD programs? Here, we attempt to understand the benefits of such programs in terms of learning outcomes and of target population.

What are the specific challenges linked to distance PhD programs (as compared to other distance university degrees), and how can we attempt to address them?

What methods should be explored in order to ensure quality of learning but still favor autonomy and creativity?

Introduction

We are concerned with the design of distance PhD programs. Within PhD programs, we can distinguish those aimed at training highly skilled specialists, and those aimed at training researchers. Our focus is with the latter: the PhD process as research training.

The doctorate at a distance (or D@D) is a topical area, which currently fuels much interest from governments and universities (Averous and Touzot, 2002) (FU.NT Expert Work group, 2002) (National Science Board, 2002). Benefits sought include:

- An increased accessibility for potential students, which is a motivator for distance education in general, but which is specially relevant at the PhD level, in the context of "knowledge economies";
- The merging of PhD programs which, individually, may have a small number of students, but which attain critical mass when merged;
- The promotion of distributed research, which is actively encouraged and rewarded by research funding organizations. Distance PhD programs can help introduce a new generation of researchers to the practice, tools and methods of distributed research.

Despite this interest, there is currently little work in this area, either theoretical or in terms of best practices from the field. Indeed, work in distance university training focuses on *professional* training rather than on *research* training, and work in such areas as virtual research communities focuses on the *practice* of research rather than on the *training* of researchers. As to actual experiences, there are some existing distance PhD programs, but no synthesis – guidelines or principles – that might help guide the design of such programs. A reflection on distance research training remains to be done, and we hope that this paper constitutes an initial contribution.

Initial Reflections On the Nature of Research Training

In this section, we attempt to understand the nature of training for research, in order to assess whether a systematic approach to instruction design for the D@D is possible.

At a high level of abstraction, we consider the objective of research training to be the development of the capacity to contribute to the advancement of knowledge in a given area (which may be multidisciplinary), according to the norms defined by the research community. These norms, which are defined in a collective and consensual way, must thus be known and applied to the advancement of knowledge.

We consider the advancement of knowledge to be manifested in two ways: by conducting research projects that respect these norms, and also by the critical application of these norms to research projects conducted by others. In the first case, the contribution of the researcher is direct and active, and must be submitted to peer assessment. We qualify this as the *active* role of the researcher. In the second case, the researcher must apply meta-knowledge: the quality norms of research must be sufficiently understood and mastered to allow the constructive appreciation assessment of research projects. We qualify this as the *assessor* role of the researcher.

In the active role, in order to carry out a research project, the researcher must first conceive a research problem, which means identifying and stating a problem which is new, for which there is no obvious solution, which can be investigated using a scientific method, whose relevance can be convincingly argued and which builds upon existing scientific knowledge. The next step is to plan and execute the research project: design ways to approach the problem, choose one or several appropriate methodology/ies, execute the plan in a correct and ethical fashion, interpret results and draw conclusions. The last step consists in communicating research results in the appropriate channels, using the format of scientific communications.

In the assessor role, the researcher must be able to apply the norms of the scientific community to the activities that pertain to the carrying out of research projects (as described above), and to communicate the assessment (in order to advance the community).

In addition to these basic research skills, the doctorate student must also be trained in skills that are required from the context in which research will be undertaken in their professional life. Here, we can distinguish academic careers from organizational - industrial or public (governmental) - careers. Future academics should be trained in pedagogical skills and in raising grant funding. Future industrial researchers should be trained in issues pertaining to the commercialization of research results, including the protection of intellectual property, and in the management of research teams.

Finally, researchers should also have a deep knowledge of their domain area, of its concepts, theories and state of the art, and of that of the sub-domains that constitute it.

We have found that these reflections on the role, nature and activities of research lend themselves very well to their encapsulation in a hierarchical competency profile. We are currently developing such a profile, developing and building upon the initial reflections we have exposed here[1]. To our knowledge, there is currently no competency profile for researchers. Our undertaking, presented partially in this section, is the result of a synthesis of the following sources:

- general objectives for doctoral training (Prégent, 2002),
- requirements for admission into post-doctoral training, and criteria for the granting of post-graduate grants and scholarships (Economic and Social Research Council, 2001), and
- the definition of training objectives for some PhD programs (e.g., Missouri University, 2002).

Further Challenges

In addition to training of the specific competencies that researchers must demonstrate, as sketched in the previous section, PhD training displays specific features that distinguish it from other types of training, and that should have consequences for the design of distance PhD programs. We review them here.

- PhD programs aim at training self-directed, autonomous workers, who can demonstrate leadership. Indeed, PhD graduates are often required to supervise or guide undergraduate or master students. PhD training should include components specifically linked to the development of autonomy and leadership.

---

[1] Lack of space prevent us from showing an extract of our competency profile, but this will be shown in the presentation at the conference.

- The interaction between PhD students and their research environment (peers, researchers, seminars, facilities, etc.) is an essential aspect of the training. In a distance mode, tools and facilities that support the emergence and maintenance of communities of practice and of communities of learners should be investigated.
- Another essential aspect is their interaction with their research supervisor and with their mentor (who may not be the same person. In fact, studies suggest that these interactions are more effective when mentor and supervisor are indeed not the same person (McCall and al., 2000). Studies show that the reactivity, relevance and regularity of these interactions are factors that can influence the success or failure of PhD studies (Muirhead, 1999), (Council of Graduate Schools, 1998) (Walker, 1998). Studies also show the importance of establishing trust early in the process ("swift trust" – (see Hiltz and al., 2002).
- The writing of the thesis is a critical stage in PhD studies. Indeed, it is at this stage that most of the "drop-outs" occur (National Science Board, 2002). The writing stage should be a time for monitoring and encouragement, notwithstanding the next point.
- PhD training requires "mental space" for the elaboration and maturing of ideas. A training environment where student progression is monitored too closely is not conducive to research training objectives, and can be a de-motivation factor for adult and autonomous students.
- The undertaking of a PhD program is a process that is deeply personal and meaningful, and that requires a high level of commitment (Prégent, 2002). The aims, activities and resulting career paths of PhD programs should be strongly coherent with the personal project of the PhD student.

These specificities all point to the fact that vital to successful PhD studies are a sustained contact with a stimulating research community, peer interaction, mentoring and the guidance provided by the supervisor. Learning outcomes should emerge naturally from these contacts, interactions and supportive relationships within the PhD environment, in a process that we qualify as *serendipitous.* The challenge in the design of distance PhD programs will be in the delicate balance between *engineering* learning outcomes, which is a proven way to ensure quality, and making room for *serendipity*, required at the PhD level.

Conclusion

This paper points to the need to assess the scope of applicability of an instructional design approach to the design of distance PhD programs. We have argued that an instructional design approach can be possible and beneficial, provided that it makes room for serendipitous creativity, which is the essence of research apprenticeship.

A Model LAN to Mimic the Networking Environment in Hong Kong Primary and Secondary Schools for Teaching and Learning

Ka-man Pang and Simon So
Department of Information and Applied Technology
Hong Kong Institute of Education
10 Lo Ping Road, Tai Po, N.T.
Hong Kong SAR, China
E-mail: {kmpang | swwso}@ied.edu.hk

Abstract: With the surging demands for the use of network-based learning environment in primary and secondary schools, the knowledge and practical skills on school LAN management is increasingly critical for our pre-service and in-service IT teachers. Many of our IT graduates will assume the role of IT coordinators in their employed schools on top of their regular teaching duties. Training on network concepts and hands-on communication skills are essential to them. As the prime business of our Institute is teacher training, it is impractical to provide the students with the comprehensive network training similar to network engineers, We should focus on the training to the prescribed network infrastructure in our government-funded schools. In this paper, we describe our model LAN project for teaching and learning. The model LAN stimulates a school's networking environment so that our student teachers can acquire the relevant knowledge and practical skills very close to the real school networking environment.

Introduction

Under the Hong Kong Government's five-year strategy for IT in education to promote the use of IT for the enhancement of learning and teaching (Education and Manpower Bureau HKSAR, 1998), the majority of primary and secondary schools in Hong Kong have well-established and fairly standardized network infrastructures. The networked areas include 1) Staff Room (limited to two only), 2) Computer Room, 3) Library, and 4) Multimedia Learning Centre (MMLC) if available. Some schools may have multiple access points installed in their classrooms. The computing facilities are predominately PC-based. Microsoft Windows NT Servers or 2000 Advanced Servers are used to support the client-server environment. The configuration and the cabling system for a school (Education Department HKSAR, 2002) is specified by the Education Department as illustrated in Figure 1.

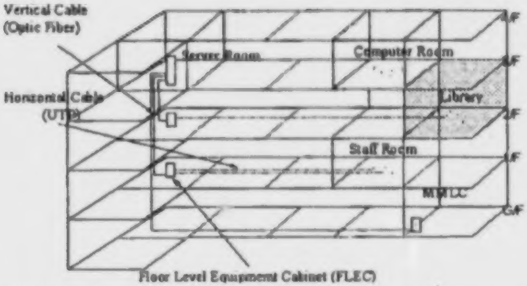

Figure 1. The Configuration and Cable Infrastructure for a school in Hong Kong (Education Department, HKSAR)

Given the unique characteristics for the school network requirement, the Hong Kong Institute of Education (HKIEd) offers a number of modules for our IT students in the areas of School LAN Management and Network-supported Learning Environment. Students are exposed to network theories, network configuration, operating system setup, web-based learning sites and a range of intra- and inter-networking concept and knowledge relevant to the school environment.

In the 2001-2002 academic year, we taught these modules and students' feedback are highlighted in Table 1. Students (over 80%) indicate that they want to practice their knowledge in a real school network which is not feasible at present. This reveals a pressing need from us to provide an authentic learning environment and, hence, the idea of a model LAN to mimic the real school environment is formulated. We proposed to the Institute for a model LAN establishment and the project has been accepted and funded.

Questionnaire(Further Comments)	Responses
The most useful aspects of this module were:	Recognize the essential network knowledge and principle
Why are they useful?	Help me understand the school network, how to setup a network-based learning environment, more confidence in teaching computing related subjects such as IT and very helpful on future self-development.
What can be changed to help students learn better:	More lectures and workshops. Doing more practice in a real network environment. Organize visit to HK school to get more exposure on a real school network. Provide a better workshop environment.
Why are these changes would help?	Practice can enhance the learnt knowledge and skill. Can understand better if learning in a real school network environment rather than from books and Internet.

Table 1. Highlight from 50 Students' Feedback

In this paper, we provide the overall design, the configuration and the salient features of our model LAN. The chief objective for this project is to foster an authentic teaching and learning environment for our

BEST COPY AVAILABLE

students. The design is also flexible enough to allow us to explore, reconfigure and extend beyond the current school networking environment.

Overview of the School Networking Environment Model (Model LAN)

In order to design an environment suitable for teaching and learning and, at the same time, provide an experience for our students close to a real school, we started with the recommendation found in the Procurement Guidelines from Education Department HKSAR (1999) as well as our experience on students' teaching practices in schools. We come up with the design topology of the school model LAN as illustrated in Figure 2. The model LAN stimulates the typical architectural design of a school in a laboratory. Four computers are grouped together in a subnet of a star topology to imitate an individual floor of a school. Each subnet is connected to the backbone switch using optical cables to mimic the vertical cabling of a school. This forms a star-to-star topology for the entire school.

External Environment

Figure 2. The Topology of Model School LAN Project

Since this is a teaching and learning LAN model, consideration must be given to the students on what the daily operations can likely be occurred in schools. Therefore, the salient features of our design include the following:

1. External access: We need to stimulate the external environment on accessing the network. Therefore, a stimulated external subnet through a router is protected by a firewall. All the traffic

BEST COPY AVAILABLE

from the simulated external subnet will be monitored by the firewall. Students will learn the important concept of security and the firewall setup activities.

2. Flexible configuration: We need to demonstrate to the students that it is possible to detach the three individual star networks / floors from the backbone switch. This is a very likely scenario in a large network when some segments are failed. Students can learn how to keep the network alive. Furthermore, by separating these star networks, we can support three small group workshops on the client-server networking model simultaneously.
3. Expandable features: We need to accommodate the latest development in schools. Campus-wide wireless communication is getting popular in schools. Therefore, the provision of wireless access point connected to the backbone switch allows the students to learn the configuration and setup of accessing the servers through wireless notebook within an accessible range. Traffic from this access point is monitored and coordinated by the proxy server. The concept of setting up a web-based portal in relation to the proxy server can also be learned in this configuration.

Conclusion and Future Work

This paper describes the model LAN project is currently undertaking in HKIEd. We are confident that this project can enhance the learning of our students on school LAN management. The model LAN will be used in the 2002-2003 academic year. By then, we can assess the learning outcome of this project.

The School Administration and Management System (SAMS) developed by the Government forms an integral part of the daily operations for teachers in schools. In the future, we need to enhance our model LAN by attaching another Virtual LAN to our model LAN to facilitate this type of networking facilities.

Adaptation Architecture for Adaptive Educational Hypermedia Systems

José M Parente de Oliveira
Clovis Torres Fernandes
Computer Science Division, Technological Institute of Aeronautics
Brazil
{parente, clovis}@comp.ita.br

Abstract: Several Adaptive Educational Hypermedia Systems (AEHSs) have been described in the literature. In general, the adaptation mechanisms are presented but the architecture of these systems do not clearly separates the several components involved. As a consequence, these architectures neither facilitate the understanding and reproduction aiming at implementing new models of AEHSs nor offer a frame of reference for comparison and analysis. This paper presents a proposal for a generic architecture for AEHSs. On the basis of the analysis of AEHSs using the proposed architecture, it is expected that the architecture be a safety reference for the analysis and implementation of new AEHSs.

1 Introduction

Nowadays there are several Adaptive Educational Hypermedia Systems (AEHSs) available. The literature present them with their respective adaptation mechanisms [Brusilovsky et al., 1996; Fernández, 2000; Henze, 2000; De Bra and Calvi, 1998; Barbeiro, 2001; Weber et al., 2001]. In general, the architecture of these systems do not clearly separates the several components involved. As a consequence these architectures neither facilitate the understanding and reproduction aiming at implementing new models of AEHSs nor offer a referential for comparison and analysis. The main focus of this paper is to present a proposal of a high level architecture for AEHSs.

The paper is organized in the following way. Section 2 presents the proposed architecture. Section 3 presents some preliminary findings from the analysis of some AEHS using the architecture. Finally, Section 4 presents some concluding remarks.

2. Proposed Architecture for AEHS

To incorporate several adaptation aspects, the architecture of the AEHSs have to clearly separate the roles of the involved components. Adaptation includes aspects of adaptivity and adaptability [Opperman 1994; Opperman et al. 1997]. Adaptive systems have the capacity of automatically modifying their own characteristics with base on their perception of the user's necessities and personal characteristics. Adaptable systems offer tools that allow the user to explicitly set certain system characteristics in order to adapt the system to user's behavior.

Figure 1 shows the proposed high level architecture for AEHSs. Such an architecture is the result of the analysis of the architecture of AEHSs and adaptive systems described in the literature [Brusilovsky et al., 1996; Fernández, 2000; Henze, 2000; De Bra and Calvi, 1998; Barbeiro, 2001; Weber et al., 2001; Opperman, 1994; Opperman et al., 1997; Karagiannidis et al., 2001]. The explanation of the Interface Component is out of scope of this paper. The architecture's components are described next.

Interaction Analyzer

The Interaction Analyzer has two main functions [Karagiannidis et al. 2001]:

- To monitor learner-system interaction in order to get information on links that have been followed, selected tools, etc.

- To infer relevant conclusions on the learner's behavior, as for example if the learner wants to relate a giving concept with another one, wants more details, etc. Depending on the learner's actions the Interaction Analyzer draws conclusions that can be of adaptativity or adaptability types.

Figure 1: Proposed Architecture for AEHS.

Adaptation Decision Model

The Adaptation Decision Model is responsible for deciding *what* the system should do and *how to do* it. These decisions are based on the conclusions draw by the Interaction Analyzer. Examples of what to do are to present more details, related concepts, etc. The *how to do* part includes the selection and the activation of the corresponding adaptation mechanisms. Among these mechanisms are the two main adaptation types identified in Brusilovsky [1996, 1998]: adaptive presentation and adaptive navigation. The function of the adaptive presentation is to adapt the content of an information node of the application domain to the current knowledge level, goals and other characteristics of the learner. The function of the adaptive navigation is to help the learners to find their navigation routes throughout the information hyperbase. The system provides this last adaptation type by presenting the links for the goals, knowledge level and other characteristics of the learner.

As to adaptability, the Adaptation Decision Model simply carry out the action requested by the learner. Adaptability includes the several tools the systems offers to the learner with respect to interface, content and navigation adaptation, as well as to inspection of the learner model.

Learner Model

The Learner Model is the structure that contains the information on the learner's characteristics during the interaction with the AEHS, that allows the system to adapt to these characteristics. Among the main learners' characteristics to be considered for adaptation are knowledge level, goals, previous knowledge, experience and preferences [Brusilovsky, 1996]. Another aspect that can be added to this list are the personal characteristics that define a learner as an individual, as for example personality factors, cognitive factors and learning styles [Brusilovsky, 2001].

Hypermedia Application Model

The Hypermedia Application Model comprises two submodels: Hyperbase and Learning Submodels. The Hyperbase Submodel includes aspects related to domain modeling, metainformation on the domain and the way information is internally represented. The stored information include the concepts to be learnt, examples, exercises and distinct ways of learning evaluation. The Learning Submodel includes pedagogical aspects, guided and unguided presentation, etc. This submodel represents the type and the way the learning activities should be realized, which actually determine the learners's behavior during the activities.

Adaptation Generator

The Adaptation Generator is responsible for generating what will be presented to the learner as a result of processing the information received from the Interaction Analyzer, Adaptation Decision Model, Learner Model, and Application Model.

3 Analysis of Adaptation in AEHSs

Besides being useful for the implementation of AEHSs, the architecture presented in Figure 1 also provides subsidies for the analysis of the adaptation in AEHSs. As an example, Figure 2 presents the result of an analysis of the architecture of the AEHS ELM-ART, according to the proposed architecture.

ELM-ART, an acronym for *Episodic Learner Model – Adaptive Remote Tutor* [Brusilovsky et al., 1996], is an adaptive system for supporting learning programming in Lisp. Even though ELM-ART be considered an AEHS in this work, Brusilovsky et al. [1996] refer to it as an Intelligent Tutoring System for the WWW.

Chapter
Hierarchical Estructure of Textbook

Figure 2: A possible structuring of ELM-ART's architecture according to the proposed architecture.

In Figure 2, the Hypermedia Application Model comprises the Hyperbase Submodel and the Learning Submodel, but in fact the Hyperbase Submodel corresponds to the whole Hypermedia Application Model. The Hyperbase Submodel consists of two main components: The Lisp Concept Network (LCN) and the Learning Submodel called also the Hierarchical Structure of Textbook. The LCN represents all the concepts used in the course, as well as the relations among them. Every concept in LCN corresponds to a page in the reference manual. In the textbook, each terminal unit, defined as Explanation, Example and Problem, treats the concepts of the textbook sections. In addition, each textbook section is indexed by the concepts of the LCN.

Since the Learning Submodel is entirely integrated to the Hyperbase Submodel, any change in the Learning Submodel in fact entails changes to the Hyperbase Submodel.

The CL-HTTP Server performs all the functions proposed in the Interaction Analyzer, Adaptation Decision Model and Adaptation Generator. Such a integration may cause some problems for carrying out system maintenance and improvements.

Besides ELM-ART, the following systems have been analyzed [Oliveira, 2002]: HEZINET [Fernández, 2000], KBS Hyperbook [Henze, 2000], AHA [De Bra and Calvi, 1998], CHA [Barbeiro, 2001] and NetCoach [Weber, 2001]. The analysis presented in Oliveira [2002] includes possible structuring of these systems using the proposed architecture, similar to the one showed in Figure 2. The following recurrent problems were noticed:

- There are no clear separation between the hyperbase submodel and the learning submodel. To some extent these two submodels are put together in a single one.
- Personal characteristics that define a learner as an individual, as previously mentioned, are not explored in these systems.
- Adaptability aspects are poorly explored. Basically they are limited to allowing the learner to define personal preferences in terms of information media and to change some aspects of the learner model related to the learner's perception of the concept mastery level.

4 Conclusion

Besides being a useful model for the implementation of new AEHS, the proposed architecture can be considered as a high level framework for the analysis of the adaptation in AEHSs. The proposed architecture fulfills the lack of a common frame of reference to such an analysis. Though the proposed architecture can drive the analysis work, it is still difficult to analyze AEHSs because of the poor system descriptions available in the literature.

The adaptation concept for AEHSs maybe could be more explored on the basis of the Hyperbase Submodel, Learning Submodel, Adaptation Decision Model, Adaptation Generator, Learner Model and Interaction Analyzer, at least to improve the systems descriptions. Maybe this can open up space to explore different levels of adaptation between the concepts of adaptativity and adaptability.

Every Word a Click: The Hypertext Being Smart

Young Park (yp85@columbia.edu),
Instructional Technology & Media, Teachers College, Columbia University

Abstract: Hypertext, one of representatives of Internet is well known for its unique features for knowledge generating activities. Now, the new types' smart hypertext is appearing to overcome current hypertext's limitations. They seem to be promising since they start developing recognizing the current Internet users' needs. The study's purpose is to investigate the new hypertext's meaningfulness on knowledge activities and to propose hypertext's future direction. And it calls researchers' attentions by asking its interrelationship with cognitive development.

The Problems

The hypertext is well known as a tool to represent rich semantic relationships. A learner builds up her memory structure by adding a new object to existing memory structure. So some factors such as proper visual association, meaningful relationships or appropriate category are very significant to enhance learning. For this reason, hypertext is very suitable to support knowledge activities.

The current hypertext is built up only by links created by a web author. It is incomplete in terms of user-centered information environment with the following reasons. Very often a web page's information can be interpreted as very different anchors from information author's original intention. It could mean that it does not provide the right response or feedback according to users' inquiry. Immediate response is one of very important factors in knowledge activities because otherwise, a user might lose her curiosity or even forget soon what she would look for. Thus, with some kinds of aids, if a user is able to construct her own hypertext-links for herself, presumably, she is able to follow her own curiosity and to facilitate knowledge activities. It could also encourage a user's flexible and creative thinking process. On the basis of such a point, I propose that the current hypertext should be more developed to be more user-centered, context-oriented and learning-focused. On the basis of this perspective, I searched the Internet and found out three new types' hypertext applications, Atomica (www.atomica.com), Flyswat (www.flyswat.com) and Microcosm (www.microcosm.com) reflecting my perspective.

The Example

Among them, Atomica, a free shareware is an exemplary one to demonstrate the above perspective. Its key point is the simple human computer interaction, which is that one just clicks on the word you want defined or explained. When a user clicks a word on where it is available, whether you're using, for example, an e-mail client, a word processor or a spreadsheet as well as Web, Atomica automatically searches its relevant information as well as definition and then opens a small window to show the list.

There is an example for understanding its features. Suppose that a user was reading an article on the Web, or an e-mail and she came across this sentence: "The abstemious people from Woonsocket invested aggressively in companies like Tecumseh Products, hoping to become as rich as their idol, John Kluge." And suppose she had no idea what "abstemious" meant, where Woonsocket was, what Tecumseh Products did, or who Mr. Kluge was. To find them out quickly using the Internet, she needs to look up each term individually, which requires her to leave the document that she was reading and laboriously type in each term for multiple searches, probably at multiple sites. Instead, she could use Atomica that fetches such answers from the Internet, without leaving the text she was reading. Also, Atomica combines the ability to search multiple information sources simultaneously with a natural intelligence that helps to ensure targeted results. Users don't have to memorize Boolean logic or even construct an English language query. For the kinds of information Atomica is designed to parse-word definitions, language translations and company profiles-it works well.

Finally, one of the most distinguishable elements of Atomica is trying and guessing the entire phrase or context of a word that a user clicks on although it is still very limited. If, for example, a user clicks on either word in the phrase "Supreme Court," the program pops up with an answer about the highest court in the U.S., not a definition of either word on its own. And it pays attention to capitalization. It knows that the word "polish" is something a user does to furniture, but Polish is a language and culture (Wall Street Journal, 2000).

However, the service is still a work in progress. First, it doesn't work with text inside an image. Second, it is not able to search multimedia-based information such as mp3 files or quicktime movie files. Third, while it draws on a host of reference works and Web databases, it doesn't use premiere sources, such as the Encyclopedia Britannica and major newspapers. It tends to rely on almanacs, single-volume encyclopedias and little-known reference sites, though it does use major dictionaries (Wall Street Journal, 2000).

The Suggestions and Discussion

I conducted the small pilot study with five graduate students in Teachers College, Columbia University in order to explore for the new hypertext's future direction. Based on Atomica's functions and the results of the pilot study, I propose the following directions.

First, hypertext is merging with a search engine. With it, hypertext is becoming more effective and is able to reduce users' information seeking efforts considerably.

Second, the future hypertext's success empowered by a search engine depends on, I believe, how much it understands users' intention. Namely, they should be smart enough to understand not only what a user is looking for but also the whole context where a user is. The findings of a pilot study support it. Its subjects merely used very simple search formulations. What they wanted to obtain was simply the quick and effective search results and not-so-complicated human-computer interaction. Hence, the concept of 'agent software' is inevitable one so that it can play a role like a secretary or a task manager reducing human users' cognitive overload to a certain degree that they feel comfortable. At the same time, such agents will restrain information overload by filtering and analyzing information on web pages.

Third, when the smart agent, hypertext provides advice or a hint to users by being modeling and doing scaffolding exactly like a teacher in a classroom, I assume that it could reduce users' unnecessary search behaviors and assist developing their' meta-cognitive process. Atomica's 'did you mean?' description or its additional key words' list can be exemplary.

Finally, while more successful information seekers seem to be able to initiate their search behaviors on their own, less successful ones need a structure to help them search and do knowledge activities. Hence, it will be worth to consider if hypertext can provide different levels' gateway or interface design according to information seeker's search capability consisted of novice, intermediate and expert.

Such a new hypertext seems to be worthy for further consideration to influence users' information search behavior. Although I have explored mostly the positive impacts of it but there should be negative impacts such as users' dependence on its smart functions. Thus, it should be pondered critically to what degree and in what ways it would support human beings' Internet search. That is, we should investigate its multi-dimensional aspects carefully. I hope that this study could draw educational researchers' attention to explore its roles and potential to build up the enhanced learning environments.

Abstract : Designing and developing simulators as a learning tool is an essential aspect of computerized learning systems. Yet such computerization must be well thought out and simulators designed for this purpose must be a useful and effective alternative to using the real systems they simulate. We therefore propose a simulator design method based on a simple, modular and above all generic and reusable architecture. This design method can therefore be applied to a broad range of fields and offers an efficient solution to various problems such as 1) economic factors, since a simulator is often less expensive than the system it simulates; 2) geographic constraints, since it can be utilized almost anywhere; 2) grasping certain concepts, since it can focus on interesting aspects and results by getting rid of numerous technical problems; 3) lastly, it lightens the educator's workload by assisting the student using the system. As well, the widespread use of *Java* allows for a quick, simple and efficient implementation of such simulators, especially due to its multi-platform properties, the modular nature of its *JavaBeans*, the ease with which the encapsulation of variables is executed and the inherent self-analysis possibilities of this language. Yet it should be pointed out that *Java* still exhibits problems, especially in regard to sluggish execution speed and insufficient security management.

Introduction

Over the last few years, there has been an explosion and widespread use of communication technologies, and of the Internet in particular. Thus there is an easier access to these new technologies, from an intellectual and an economic point of view. Educational and teaching institutions have welcomed this electronic revolution, since some educators have long dreamed of the benefits of computerizing learning systems (Paquette et al, 1996). In fact, they have in many cases already explored this approach, and have encountered numerous problems: an inadequate and heterogeneous infrastructure of materials and software, insufficient processing capabilities and above all, insufficient design and development tools. As a result, numerous specific learning objects have been created independently: on-line courses, student evaluation tools, interactive tutorials or virtual laboratories systems often based on simulations or remote access to real apparatus (Saliah et al, 1999). Let's recall that a virtual laboratory is a space where several people can run experiments based on real or simulated data and materials, while being totally free of geographic constraints This paper will deal with the latter type of computerized learning system. Developing reusable pedagogical and modular software simulators of real systems offers several advantages: 1) It helps students grasp the fundamental concepts of a system by getting rid of material problems such as bad contacts in electronic circuitry, handling hazardous products, lengthy and laborious handling of material; 2) It offers automatic assistance during the learning process by providing students with advice and relevant information at the appropriate moment; 3) Lastly, it resolves economic or physical problems involved in accessing to costly materials, by simulating and integrating real materials within the context of *virtual laboratories*.

Software solutions have been available for some time and propose remote access to various devices (National Instruments, 1998) and (Sigmon and Davis, 2001), yet they incur numerous problems: utilization limited to a specific field, complicated utilization, difficult integration with a computer-assisted learning system (CAL) (Saad et al, 2001). As a solution to these problems and requirements, in this paper, we are proposing a generic simulator model for training and learning within virtual laboratory environments based on reusable Java components (Matena et al, 2001). In the following sections we will describe the architecture of the proposed modular and generic simulator model.

A Simple Case Study: An Helicopter Altitude Control System Simulator

Requirements

In order to clearly describe the basic components and advantages of our model, we propose designing an helicopter control system simulator. We wish to develop a Distributed Computer Aided Learning application that copes with the specification described in table 1. These specifications let us henceforth predict the functions that should exist in our simulation application.

Table 1: Specifications and Functions Sought

Specifications	Functions Sought
To simulate an helicopter altitude control system	• simulation functions of the system based on mathematical algorithms and equations modeling the proposed filters. • set of variables representing the simulated system state
Lets the user interact with the system parameters during the simulation	• user interface reacting at any time during the simulation • immediate feedback of any modification • control of transition states from setting to setting, as required
lets the simulation be conducted automatically according to a pre-established scenario	• scenario manager
can run this simulation in real time by means of a real data acquisition system; Data can be acquired from a remotely located site through computer networks can export simulation results to an external software.	• input/output control • capability of importing signals, doing calculations and exporting results in real time; and configurable data acquisition system

Generic Model Proposed

The generic interface has three windows (Figure 1). The first allows the input of the physical model's parameters. All the controller parameters are defined in this window and they can be changed during the simulation. The second window is designed to animate the physical representation of the system. For example, figures 2, 3 and 4 shows respectively simulators of a tank, a submarin and an helicopter control system within the same interface framework. Finally, the third window gives a brief explanation of the theory related to the system, the diagram bloc and the time domain results. The diagram bloc illustrates the control loop. In the case of the helicopter altitude control simulator (Figure 4), R(z) is the set point signal, E(z) represents the error between the set point and the measured output Y(z). The error is then applied to the controller to compute the control to be applied to the system. In the case illustrated above, the controller structure is a PD type controller with the following transfer function $G_c(z)$ in the z-domain:

$$G_c(z) = K_P + \frac{K_D}{T}\frac{z-1}{z}$$

where K_p and K_D are the proportional and derivative controller gains and T the sampling period.
The output Y(z) is related to the control U(z) by the following relation

$$\frac{Y(z)}{U(z)} = K\left[\frac{T}{z-1} - \tau\frac{(1-e^{-\frac{T}{\tau}})}{z-e^{-\frac{T}{\tau}}}\right]$$

This architecture is comprised of the following five main modules:

The System State Module

The *State variables* contain the information representing the simulated system state. These values are memory-resident and can be consulted and modified via the *Simulator, Input-Output, GUI* and *Scenario*

BEST COPY AVAILABLE

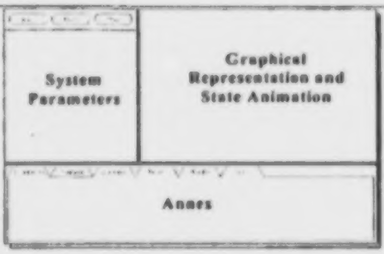

Figure 1 The Generic Interface Model

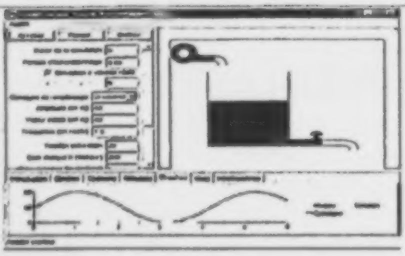

Figure 2 A Tank Simulation Interface

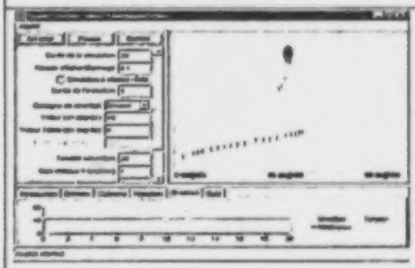

Figure 3 A Submarin Simulator Interface

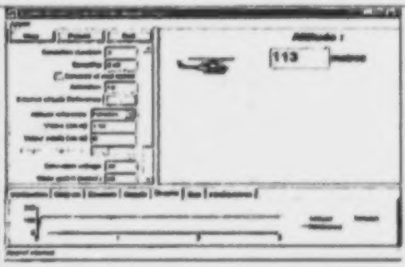

Figure 4 An Helicopter Simulation Model

Manager modules. In the highly unlikely event that a state variable might be simultaneously modified by two modules, protecting concurrent access to the variable by means of mutual automatic exclusion would be advisable. The *write controller* sends events to other modules when the value of a variable being utilized has been modified

The Simulator Module

How this module works can be clarified in figure 7. The *simulation model*, specific to each application, contains the code needed for the simulation itself. This simulation will generally be based on a set of mathematical formulas and other constants. The *GUI pilot*, also specific to each application, gives a graphical rendering of the simulated system state by driving the *GUI*.

The Graphical User Interface

The *GUI construction module* represented in figure 8 utilizes set data to define all components to be loaded on starting the application. It creates the startup screen and all windows or components that could be utilized during the simulation. The *standard and intelligent component library* provides various types of visual or non-visual components. Each component will possess some input data (title, style, etc...) and output data (values). Interacting with these components (click, value modification or entry) will automatically generate a *system state* modification, according to the new state of this component.

The Input/Output Module

The *exported data management* module exports data generated by the simulator. It controls the entire process such as the connection with external applications, the accessibility, data transfer (sending) and traffic flow security. The *imported data management* module, on the other side imports data generated from external sources and useful to the simulator. It also controls the entire process but deals with the received data instead.

The Scenario Manager Module

The scenario manager's role is to drive the simulator according to a pre-established scenario or according to a user-generated scenario. Here, the Graphical User Interface (GUI) Pilot is a set of functions allowing the user to edit scenarios and control their execution.

Conclusion

Computer Aided Learning applications are fast becoming an essential learning tool. Simple, modular and generic simulators represent a solution for various problems: economic factors, geographic constraints, grasp of certain concepts (understanding the fundamental notions involved), avoidance of having to deal with real equipment, efficient follow-up of student progress. We have used JAVA, a computer language, to demonstrate our concept of generic control system simulator. The model can be used for applications other than learning. This design method is not limited to the teaching area and can very well be utilized in developing all types of simulators, be they stand-alone or part and parcel of a virtual laboratory.

BRIEF PAPER ABSTRACT

Title: A District in Transition: Information and Decision-Making in a California Community College

Authors: Dr. Lisa Petrides and Sara McClelland, Teachers College, Columbia University
Email: lap52@columbia.edu

BACKGROUND

Information systems play a critical role in assessment and accountability. In order for educational institutions to develop effective methods to evaluate strategies that improve student outcomes, a reliable and accurate system must be in place for collecting and disseminating data. These data, in turn, must be readily accessible and put into formats that are easily understood and used. Finally, staff must be willing and able to use data and have the ability to inform and modify policy and practice accordingly. Unfortunately, most community college districts have no reliable methodology to evaluate the effectiveness of resource allocation in improving student learning. However, state and national trends are clearly moving in that direction—improvement of assessment and accountability research.

This study examines the ways in which faculty and staff within a community college district interacted with student information in making day-to-day decisions and engaging in long-term planning. The goal of the research was to better understand the intersection of cultural, political and technological forces within the district as they faced an increased demand to use data, information, and knowledge to account for monies spent and decisions made. Current organizational change research shows that effective use of data and information can raise performance, productivity, and outcomes at all levels – for students, faculty, administration, and governance. Therefore, an institution that collects and uses data on student performance can proactively make decisions about investments in programs and services, target remedial assistance, eliminate duplication in programs, and ensure higher rates of student success.

METHODOLOGY

Due to the increase in state-mandated accountability measures and the desire for internal research, this study examined the use of data to inform decision-making in one California community college district. We were interested in identifying the issues that arose out of the desire to use information about students to inform decision-making; specifically, the types of student information that were required, how information was produced or accessed, the quality or usability of the information, and how the information was used once it was received.

The research team conducted 49 in-depth interviews with administrators, faculty, and staff at one community college district. We used the critical incident technique that allowed us to elicit examples and outcomes by gathering information about actual behavior that relied upon specific recall, thereby bypassing opinions and hypothetical situations. By asking people to recall specific incidents, gathering information about the context of those incidents and asking whether the incident had a successful or unsuccessful outcome, we were able to take a snapshot of what types of information had been requested over the past year and to identify the processes undertaken by information seekers to get information on students. We selected our interveiw samples based on a cross section of administrators, faculty, and staff members who were chosen because of their involvement in decision making processes. The critical incident methodology allowed us to examine: 1) the beginning and ending of a critical incident; 2) a task or goal of a user just before critical incident occurred; 3) expectations of user just before critical incident occurred; 4) a detailed description of critical incident (what exactly happened, what caused it); and 5) the severity and frequency of the critical incident

We employed a non-random selection process that included:

1. Administrators: The high level officials who oversee the management of the campuses
2. Faculty: The teachers who are also involved in decision making bodies on the campus such as deans and program coordinators
3. Staff: The assistants and aides who support the faculty and administrators and therefore are often the ones who do the legwork to find out student information

FINDINGS

The first theme that we found was the presence of a very strong research culture within the district. Individuals have a strong desire to find out how they can help students and a highly developed ability to craft insightful and focused inquiries. However, historically necessary data and resources have not been readily available. As a result, this desire to improve outcomes has often been hindered as faculty, staff and administrators struggle to find data that can be used to make informed decisions concerning students. Said one participant:

> *I can't even tell you how many students survive a class here. I have no idea. Does this make me feel good as a manager? Absolutely not. I feel like I'm trying to manage in one of those black hoods where you're just kind of feeling - is this an elephant? Is this a giraffe? What do I have a hold of? And I'm trying to do my best guess.*

Instructors and administrators alike have a strong desire to acquire meaningful data to become more effective in their jobs, yet this desire has not been appropriately supported or aided by the existing student information systems. More often than not, data are fragmented, scattered, and incomplete. One participant commented:

> *[T]here's more than one system tracking student data and they don't -- they're not the same. They don't yield the same data. So is it valid? Is it reliable? Can you count on it? Can you do projections? Can you do reports accurately? Probably not.*

Additionally, access to and flow of information remains inconsistent across departments. Technology infrastructure and capabilities are insufficient to support the increasingly complex needs for meaningful information. As a result, existing data fails to inform its users in ways that enable them to decide where to invest resources and which programs need to be improved. Most are forced to rely on hunches about student performance rather than rely on multi-variable student data that are continuously collected and analyzed. This translates to lost opportunities on each campus—lost time and energy having to create smaller but more accurate systems, lack of long-term planning data, difficulty with enrollment management, problems in assessing student outcomes and establishing benchmarks for comparison, and an inconsistent ability to substantiate needs for further funding. This ultimately impedes progress in the development of appropriate learning environments or interventions for students.

This culture of inquiry has been historically hindered by the lack of available data resources. In the face of this deficiency, many individuals have developed ways of working around this problem and have created their own data, in the form of separate databases, internal student data, and sometimes resorting to methods such as hand counting students in classrooms because they believe an accurate and timely count could not be retrieved using the existing technology.

> *Well, we all use Excel. We all use our own spreadsheets. We do all that. I mean, that's what we do.*

Although this means there is a strong desire to acquire meaningful data in order to be effective educators and administrators, this desire has not been appropriately supported or aided by the existing student information systems. This translates to lost opportunities on each campus—lost time and energy having to create smaller but more accurate systems, lack of long-term planning data, difficulty with enrollment management, and an inconsistent ability to substantiate needs for further funding. This ultimately impedes the district's progress in the development of appropriate learning environments or interventions for their students. They are forced to rely on hunches about student performance rather than rely on multi-variable student data that is continuously collected and analyzed.

> *Interviewer: How are you able to, I mean, what are examples of situations in which you find yourself needing to make a decision, needing data, and what mechanisms do you devise in order to do that?*
> *Participant: Shoe leather, conversation, and just my best guess. That's all I've got.*

All of these factors impact this community in a number of important ways. First, students are not served to the fullest. Second, this district is not spending its limited resources effectively. If staff are forced to hand count students, this is time and energy that is taken away from many other important tasks. Third, they cannot plan for the future when they are not sure what has worked in the past. They cannot develop new strategies for growth and change with the times when they do not know what programs are shown to positively impact student success. They simply do not have enough information to know what works and what does not.

> *Interviewer: And are you able to notice any distinguishing characteristics among those students who are failing? Is that kind of information-- Participant: That's the information that we're not getting. We're not breaking it out. We're not breaking it out by ethnicity, or by course, or by gender, or any of those kinds of things. That would be helpful information to know how to target what to look at, are there special populations that are encountering these kinds of issues. And if so, then you identify the population and look at that population and say, 'Well, what are the barriers? What can we do to create interventions?' But we're not getting to that depth utilizing the research information to get to that depth to problem solve.*

CONCLUSION

We believe that the ability of administrators, staff, and faculty to obtain the information they need to make informed decisions about their academic programs and services is criticial to student success. As researchers, we started with a basic assumption that the accumulation of data is influenced by the core values of the organization, and that these data, through human interaction, take on significance as information. Our findings indicate the importance of research in the field of education that can help us understand how and if data are transformed into information and then knowledge, and finally, how this process informs decisions that contributed to positive student learning outcomes.

Research concerning how groups manage data and information in order to make decisions has long been popular in other contexts, outside of higher education. There has been a great deal of recognition in the business world, for example, that information and knowledge management can be vital tools in organizations. However, it is only recently that institutions of higher education have begun to look at how they might more effectively use information systems for better management practices, as well as in teaching and learning environments. Because much of the literature on knowledge management in business is focused on economic utility and consumerism, studies that focus on the field of education are important in order to ensure that issues of student success in terms of democracy (such as information sharing) and social justice (such as access and equity) are kept in the forefront.

CORE SOLUTIONS: A TRIFECTA FOR EDUCATION

Abstract: In the central Florida area, the School District of Osceola County, the Valencia Community College and the University of Central Florida have designed a partnership program to give employees of the school district the opportunity to complete a baccalaureate degree. This paper addresses the current shortage of qualified teachers, the need to recruit and retain teacher education candidates through a mutual effort by universities, community colleges, and school districts, and the need to attract a more demographically representative minority population to teaching. The paper also presents the existing connectivity and technological tools that support and enrich the academic experience. The program, named CORE (Creating Opportunities and Resources for Educators) is described. The presentation will include a live demonstration of the technological infrastructure affording access to library and Internet resources for all CORE students and faculty.

The CORE Program

Osceola County has a reported population of 172,493 residents. The School District of Osceola County has a population of 37,774 students in K-12 with a growth rate of 12% annually. Of these students, 35% are Hispanic and about 22% have language problems. The school district identified as one of its highest priorities the recruitment of a diverse pool of teachers to meet the needs of a diverse group of students. To accomplish this, the Superintendent of the School District of Osceola County and the President and Provost of Valencia Community College contacted the Dean and Associate Dean of Education at the University of Central Florida to form a partnership that would give employees of the school district (non-instructional personnel) the opportunity to complete a baccalaureate degree in Education.

The CORE Program (Creating Opportunities and Resources for Educators) is a collaborative partnership formed by a metropolitan, research university, a community college (a Hispanic serving institution), and a school district with a Hispanic population of 35% that is experiencing a critical shortage of teachers. The purpose of the CORE Program is to address the critical shortage of qualified teachers by assisting non-instructional personnel in the district to pursue a degree in teaching. It is based on the premise that the accountability for solid educator preparation relies on the mutual efforts of university, community college, and school district faculty and administrators; business leaders; legislators; members of the media; private foundations; counselors; advisors; and financial aid officers. The purpose and outcomes of CORE underscore the need for collaborative efforts among diverse partners to address the national shortage of qualified teachers. The CORE Program has promoted the success of all its students by assisting them to overcome the obstacles of distance and time, learning in isolation, problems accessing technology, and difficulty with paying tuition.

CORE participants who live and work in the county have excellent access to lower division college classes at the local community college. The community college campus is located in the heart of the county's most populous area. The CORE Program offers a class schedule that accommodates the needs of the participants who are faced with the difficulties of working full-time, meeting their family commitments, and taking classes. CORE participants also have access to specially designed online classes that facilitate flexible time scheduling. For many potential teachers, the prospect of completing their studies at a senior institution is complicated by the fact that the local university is over 40 miles away. For CORE participants, the university offers the baccalaureate degree right on the community college campus with selected courses provided through distance education. In addition, CORE participants complete required field experiences and internships in their own school district.

One of the greatest challenges non-traditional students face is the fact that they have to fight the uphill battle of getting an education without an extensive support network. The CORE Program has created a community of learners by giving every participant a mentor, a teacher or administrator who works in the same school. CORE participants stay connected with others through their own dedicated web page (http://faculty.valencia.cc.fl.us/CORE), which contains a discussion board for their exclusive use. In addition, a community college member stays in contact with each of the students each semester to make sure that everything is going smoothly and the university sends professional advisors to the community college campus to provide advisement. CORE participants complete the program as members of a cohort making it possible for the participants to form study and support groups.

Students cannot take advantage of web pages, online classes, or the riches of the Internet if they do not have computers. Every CORE student who needs one is able to have a computer at home. The community college provides the computer and the school district equips the computers with modems, thus helping to close the digital divide between the technology haves and have-nots.

Since time is critical for CORE students, it is essential to provide them with a fully articulated curriculum. The CORE program provides participants with the opportunity to earn an Associate of Arts degree, thus guaranteeing them junior status at the university. Furthermore, this curriculum meets every transfer requirement for the university's Bachelor of Science degree in Elementary and Exceptional Education. The CORE Program guarantees a seamless transition between the two academic institutions.

Closing the Digital Divide

Convenient efficient program models, realistic course loads, mentoring, and schedules tailored to meet the needs of working adults are essential to student success. Academic information, i.e., electronic access to student services and to academic and library resources, is also crucial. Particularly in the CORE program, many of our students reside outside the metropolitan area in communities where they maintain employment and families. A large part of our commitment to high quality education rests on developing technological tools and staff training to provide convenient remote access to multiple information services. In an earlier work the authors discussed access to admission, class schedules and registration (Stahley and Platt, 2001), the following portion of this presentation will examine live, online information access strategies in place at the community college and the university to afford access to proprietary educational resources, library catalogs, and help services.

As CORE students begin their coursework in pursuit of the associate's degree in education, their best option for electronic research access is Valencia Online (VO), http://west.valencia.cc.fl.us/distance/lrc.html, a site brimming with useful information including bookmarks for style guides, and full-text and citations databases accessible to any user equipped with an Internet Service Provider (ISP). Valencia Online was designed for distance learners. The site, however, and supporting links present not only LRC catalogs and proprietary database gateways, there are also countless tutorials and guidance services tailored to meet any research need. As such, VO is an invaluable asset for meeting the needs of all VCC students and faculty.

For example, the VO page includes a hierarchical menu of resources beginning with the Library Card link. Here is found is information about the 14-digit number required for access to licensed databases, as well as a listing of the other services and resources that require a library card. Next is a search guidance hyperlink to the community college catalog. The Online resources link leads to research bookmarks and electronic databases chart. Research Bookmarks presents a tabular list of indispensable reference works for the student researcher ranging from APA and MLA style guides, to full-text encyclopedias, to a multimedia archive of photos, audio clips, and graphs dating back to the 1920s. The electronic databases link is the gateway to a matrix listing of databases, complete with subject coverage, information type, update frequency, format, and a hot link to the database. One of the most valuable links at the Distance Learning site is to be found at the Internet Resources page. After a succinct caveat related to evaluating Internet information, the list begins with an 4part information literacy tutorial on selecting a topic, searching for information, and evaluating and documenting resources. Several other useful and relevant links are on the list, including a step-by-step research guide, a search engine strategies chart, and a guide for citing electronic resources. Last, the Distance Leaning page describes "bread and butter" services, such as document delivery services, and descriptions of each Valencia Campus Learning Resources Center Collection, with areas of subject emphasis to give students and faculty an idea of "what is available and where."

Once students make the seamless transition to their upper division CORE studies, the knowledge, skills and experience acquired from Valencia Online provides the foundation for utilizing the University of Central Florida library and information services. The countless resources of UCF libraries are accessible via the Internet. The size and complexity of the available databases makes them slightly less intuitive and user-friendly than Valencia Online. Still search guides and user assistance are generously sprinkled throughout the system. In addition, like the VCC system, UCF licensed information is protected and accessible only by students, faculty, and staff. Several levels of system entry are available, ranging from baseline ISP access, for book catalogs and non-proprietary databases, such as ERIC, to proxy access to most information and services, to full-blown, comprehensive access to every database and service via the University's network, Pegasus server.

For CORE students, the University Libraries homepage, http://library.ucf.edu/, is the starting point for education resources access. Corresponding to VCC's resources pages, the UCF library's page lists a hierarchical index of resources beginning with book catalogs and WebLUIS services. Following is a link to journal articles and other resources. Clicking the articles and other resources link takes the researcher to a tabbed listing of 18 subject-specific resources links beginning with popular databases and ending with social sciences databases. Clicking on the education subject tab takes the researcher to a hot-linked listing of full-text and citation databases designed to fill the research needs of students and educators. In the Education page header is a link to a dozen user guides for education classes. Some of the most useful educational resources links are the six areas mentioned in the table below below. All of the guides are worth examining.

UCF Online Education Resources

Link Title	Access To	Comments	Hyperlink to Resource
Education and Elementary Education Resources	Book catalog by classification range and subject databases and indexes for education topics.	Includes description and access needs.	http://library.ucf.edu/Instruct/Education/UserGuides.htm
Education Webliography	Comprehensive access listing of 28 education-oriented sites, including curriculum and instruction, elementary education and middle school, technology in K-12, mathematics and science, and multicultural education.	Most sites include annotation.	http://library.ucf.edu/Instruct/Education/eduwebsites/education_webliography.htm
Internet Tools	Hot linked listing to research resources for searching and evaluation of Internet sites, and an annotated list of popular and meta, image, and education search engines. Also includes children's search engines and a site for search engine comparison and evaluation.	An irresistible gateway to everything you always wanted to know about Internet searching but did not know how to ask.	http://library.ucf.edu/Instruct/Education/EDF6481/internet_tools.htm
Music Webliography	Comprehensive access listing of 25 music education-related sites, including church music, American music, composers, ethnomusicology and world music.	Many sites are annotated. Also include sites for lyrics and public domain music. Note: ".com" usually designates a pay-for-access commercial site. Look for ".edu," ".gov," or ".org" sites.	http://library.ucf.edu/Instruct/Education/musicwebliography.htm
Psychology Subject Guide	Comprehensive listing of 13 psychology guides, including access to online journals, texts, APA resources, directories and associations.	Many sites are annotated and include resources at other universities.	http://library.ucf.edu/Instruct/Education/psychology_subject_guide.htm

Table I: Illustrates online education resources available from the UCF Library Homepage.

Conclusion

CORE is a program that exemplifies the role of shared accountability in education implemented by university, community college, and school district partners in central Florida as they identify potential teacher candidates and shepherd them to successful completion of a collaborative teacher preparation program. The CORE Program is dedicated to the mission of finding potential teacher candidates and helping them become successful, while at the same time relieving the shortage of qualified teachers that exists in the community. To ensure that CORE students have optimal access to resources, and ultimate success in their educational pursuits, VCC and UCF have designed and engaged a system of electronic and Internet access and resources tailored to suit education-specific lower and upper division coursework.

Handouts will include the presentation slides and a list of partnership, and education resources web sites.

Online Learning Forum:
An RPInteractive Professional Development Model

Abstract: This paper will describe the Online Learning Forum (OLF), a k-12 professional development program. This RPInteractive professional development model provides teachers with the opportunity to learn new technologies, work collaboratively, communicate with their peers, and develop projects for their classrooms. With the advent of distance learning, online teaching and learning allows educators to participate in such experiences at their own pace, in their own environments, on their own time. This model has been developed to facilitate a community of learners, where the transfer of existing technologies and the development of new technologies are integrated into an RPInteractive experience unlike any other.

Background

This model of online professional development is a work in progress, where new technologies and new approaches to online teaching and learning inspire new pedagogies. The Capital Area Technology and Inquiry in Education (CATIE) mentoring program, also developed by CIPCE, provides a basis for the online learning forum. The CATIE model situates educational technology experts in schools and classrooms to work directly with teachers (Swan et. al., 2002). The situated professional development model is based on a constructivist approach to technology integration, in which educational technology mentors work jointly with teachers to design computer-supported lessons that incorporate technology into existing classroom curricula.

We are adapting this model into the online environment. However, the Internet's current limitations as a medium of instruction, including its reliance on text and still graphics or low-quality audio and video would seem to restrict instructors' abilities to form motivational relationships with their students (LaRose and Whitten, 2000). Research on classroom teaching in higher education found that *teacher immediacy* behaviors that increase the perception of closeness between instructors and students can increase affective learning, which in turn increases cognitive learning (Rodriguez, Plax & Kearney, 1996). Mediated instruction can also evoke teacher immediacy, but only live interactive video (Hackman & Walker, 1990) and videotape recordings have been (Guerrero & Miller, 1998) proven effective. Research on computer mediated communication (Walther, 1996; Lombard & Ditton, 1997) calls our attention to the socio-emotional deficits imposed by mediated instruction.

Although there are deficits imposed by mediated instruction, the development of new technologies and approaches to online instruction challenge us to create better web courses. To improve the 'behavior' of the computer, RPInteractive presents a new approach to online course development.

RPInteractive is an approach to e-learning being developed at Rensselaer that seeks to enhance learner-content, learner-instructor, and learner-learner interactivity for distance students (see Danchak paper submission to ELearn). As a natural extension of the Studio model (Wilson, 1994) of instruction in the face-to-face science and engineering classroom integrates mini-lectures, collaborative learning, inquiry and direct experience, reflection, and_conceptualization, in a sequence not unlike the Kolb Learning Cycle, RPInteractive transfers these techniques, as well as existing and new technologies into the online environment. The role of the instructor/coach in this model is to gauge students' understanding, listening and questioning them to develop desired knowledge_(Cupp, et al, 2001). In the online learning forum, a course Mentor guides students through an experience and models an interactive, student-centered approach to instruction.

Our Unique & Innovative Style

Integrating tools with content is the pedagogical foundation of everything that the Online Learning Forum attempts to achieve. The components described in Table 1 are integrated into the context of a topic(s) and/or a software application to meet course objectives, where communication, collaboration, and activity-based learning are facilitated.

Component	**Description**	**RPInteractive Element**
QuikQuiz©	This tool, unique to the Online Learning Forum, addresses the issue of immediacy behaviors, where the Mentor poses a question regarding a given topic, and students are to respond, after which they are immediately able to view the responses of their fellow participants. The course mentor can then view which participants are on task, and make necessary adjustments.	Communication Collaboration
Interactive animation	Another unique component of the Online Learning Forum that permits participants to follow along as the animation proceeds to sequentially access commands in the computer application being taught online.	Activity-Based Learning
Video	Camtasia is also integrated into the online learning forum experience. This allows participants to watch a demonstration of a specific objective in short clips.	Activity-Based Learning
Problem solving	These scenarios are integrated into the context of a learning activity. Project development is supported by the integration of problem-solving situations where the participants are required to analyze and critique situations.	Activity-Based Learning
Threaded discussion	This communication tool permits participants to interact with the course Mentor and course participants to share, discuss and reflect on teaching and learning with technology. Participants have the ability to access these discussions and a tree-like structure will permit them to respond to any of the comments.	Communication Collaboration
Technical orientation	This prerequisite may be completed online or in-person with a course mentor. This orients participants to the online environment and provides them with all plug-ins and downloads necessary for a successful OLF experience. Teacher attitudes and beliefs, which may affect their confidence in dealing with advances in technology and their perception of change, are also addressed.	Activity-Based Learning

Capstone project	Participants complete a project that can be integrated and implemented into their classroom and/or school environments.	Situated Learning

Table 1: Online Learning Forum Interactive Components and Descriptions.

Findings

The online, asynchronous six week experience aims to provide a forum for interaction between educators where they are able to reflect individually and as a group on technology integration, to build a network of fellow educators to develop and disseminate technology-rich resources, to share new learning and to provide hands-on experience with software applications. During the Spring 2002 semester, 27 area educators enrolled in two different online courses. An end of session online survey was distributed to course participants to determine their perceptions of the course's structure, format, content, and design.

Participants in the Online Learning Forum courses were satisfied with the course objectives, structure and course mentor. All of the participants indicated that the components provided them with the opportunity to interact with the course content at a level comparable or higher than a traditional workshop setting.

Feelings about learning online when you enrolled in the course were first captured. All participants reported reluctance, as well as excitement. Comments included:

> *"…. anticipated it would be a great way to learn at my own pace at home!"*
>
> *" I was excited about learning how to do this work."*
>
> *" I was excited by its flexibility and wanted to try it!"*
>
> *" I was nervous at first. I thought that it would be confusing."*
>
> *" I was very curious as to how the lessons would be taught and how much I would be able to do."*

As a result of the online courses, students also reported the ways their feelings changed, or remained the same, as a result of taking this course. Comments included:

> *"I still think it has the advantage of being able to work at your won convenience but there is also a matter of self-discipline creating the time."*
>
> *"I am more confident in taking another course online. Even though I did miss people direct contact."*
>
> *"I am pleased with what I have learned and the experience of it via distance learning."*
>
> *"I am amazed at how informative the course was! The examples were very clearly portrayed. I was able to apply them right away!"*

In addition, participants revealed that having an initial face-to-face orientation to the online environment course would have enhanced their experience. For these participants who have not taken online courses before, this would alleviate any initial hesitation and frustration. Participants stressed the importance of problem solving scenarios and examples. In future and existing courses, revisions will be made to include more interactive, problem solving scenarios as well as an integration of more examples of how to apply give software programs.

Conclusion

Most of the participants in the online learning forum have never taken an online course prior to this experience. Although the online learning forum allows educators to engage in technology-rich activities to enhance their face-to-face instruction, some teachers are skeptical as to whether an online experience is for them. Learning new technologies in an online environment requires that participants not only learn given content, but also become familiar and comfortable with the course design. Future efforts will be given to finding solutions to issues such as these, in addition to a continued pursuit to integrate new technologies that will improve online professional development.

Student Roles in Online Learning Communities: Navigating Threaded Discussions

Linda Polhemus & Karen Swan
University at Albany

Abstract: This paper discusses navigation strategies affecting the interactivity of a graduate level course's asynchronous online discussion with a focus on the development of a learning community and knowledge building. This qualitative analysis reports on an exploratory investigation of student interviews and observations while interacting with the online discussion board. Observations of graduate level students in education courses from the State University of New York Learning Network (SLN) in the 2001-02 academic year revealed that students were interacting with the content vicariously and that the integration of multiple perspectives facilitated the construction of knowledge both individually and communally. Routines for reading and responding to discussion board messages also suggest that first students negotiate through the threads created, then based on personal criteria interact directly or vicariously with the content of messages.

Purpose

Quantitative research provides valuable information for online teaching and learning, however, the emphasis on grade/test score improvement does not really explore what is really going on in an online learning environment. How can we identify factors that increase participation and the quality of an online discussion? How can we evaluate the navigation patterns and their influence on the dynamics of the online community only assumed in an online discussion? This study presents the development and implementation of a research and evaluation protocol that analyzes online course participation for community building indicators and perceptions of learning. Specifically, it examines the way in which a user navigates the online discussion board interface, uses 'dialogue' to compose messages and construct and develops a perception of community online.

Literature

Many believe that the defining characteristic of the computing medium, if one can think of the computer as a single medium at all, is its interactivity (Bolter, 1991; Landow, 1992; Murray, 1997; Turkle, 1997). Recent research has focused on the general topic of student interaction within four defined categories: (a) learner-content, (b) learner-instructor, (c) learner-learner, (d) learner-interface (Hillman, Willis, and Gunawardena, 1994; Moore, 1989). When at least one of these forms of interaction is incorporated into teaching, student achievement and satisfaction are enhanced (DeVries, 1996; Fulford & Zhang, 1993). a fifth interaction, that of (e) 'vicarious' interaction (Sutton, 2001) whereby students do not interact directly at all, but observe and process both sides of direct interaction between two other students or between another student and the instructor has also been suggested.

Research focusing on community describes 'legitimate peripheral participation' as a means for knowledge building (Wenger, 1998). Although peripheral participation is assumed as a result of online communication, evidence for this assumption have not been determined. In addition, working together in an online discussion is also facilitated. Students are required to respond to each other to reach course goals. This produces the externalization of the thought processes, the comparison of alternative perspectives, social facilitation, better learning, high self-esteem and more positive attitudes toward the learning experience (Salomon & Globerson, 1989).

Method

The students who volunteered to participate in this exploratory study were enrolled in graduate level courses. Over the course of two semesters, different students from different courses discussed and participated in their online courses as they 'normally' would. Our protocol involved first students responding to questions regarding discussion board participation and online community. Second, students were asked to 'think aloud' while reading and responding to required discussion for that particular module or week. Third, students were asked follow-up questions regarding their interactions with the discussion messages, why they made such decisions and what they think about the community.

Instructor expectations for threaded discussion integration into asynchronous courses are as follows:

- To make thought visible
- Negotiate meanings around content
- Exposure to multiple perspectives
- Articulate positions
- Elicit reactions
- Critically analyze content, experiences and beliefs

To determine a student's level of participation in terms of 'learning,' we analyze not only the content of their messages, but also their reaction and interpretation of the messages of others. Examples of knowledge building in online threaded discussion is dependent upon the triangulation of community development (social presence), multiple perspectives, and routines for navigation.

Community Development	Multiple perspectives	Routines for Navigation
"I feel a part of the online community of all people who've taken online courses and also a part of the smaller community that is my online course I'm taking now."	"I am excited that the information in this module correlates with an ETAP course I took last summer! I have the opportunity to draw on prior knowledge."	"First I check to see if anyone has responded to any postings I have made. Then I check out new postings. I respond to several postings, sometimes I do this randomly as to not respond to the same person all the time."

Table 1: Examples of Knowledge Building in Online Threaded Discussion

In the observations, student interactions with the structure of the discussion board, the content, their peers and the instructor were found to reflect the learning community's dynamics. In a traditional classroom setting, students are integrated with all discussions (by listening), however, their engagement with those discussions are unknown and perhaps limited. On the other hand an online discussion provides students with the opportunity to experience the interactions of others based on their own personal interests and goals. In a traditional classroom, time may not permit all students to actively participate in these experiences, nor may students be attending to what others have to say even when they are present in the classroom environment. In the online interactions we observed, when a student clicked on (and read) another's message, he or she was then either motivated to respond or not. Observations and interviews indicated that students were more motivated to read and respond to a message with which they identified culturally, professionally, or personally; to meet course requirements; to make others feel a part of the course; to anyone who responded to them; to those messages that integrated multiple perspectives.

Similar to Salomon & Globerson (1989) students reported that learning took place in the comparison of alternative perspectives. Also, as indicated by Gunawardena & Zittle (1997) and others, students were aware of other student's social presence based on immediacy behaviors. During observations, students made mention of other's negotiation patterns (such as how, where, when and to whom they posted), experiences and cultural backgrounds. In addition, students used the discussion board to 'prime' their thought processes when composing messages to others.

Video-taped sessions of students 'thinking aloud' provide evidence for the following:

1. Setting for diverse thought
2. Navigation: reading other reactions, then forming own
3. Social presence evident in posting patterns
4. Priming: reading other messages, composing, then thinking of a new response to a previous message
5. Affect: laughing out loud at the message

Follow-up interviews revealed that students feel a part of their course's learning community, as well as, part of the community of all online learners.

Discussion

When students were navigating through the discussion, they were making decisions. First, they were making decisions about which messages to read. When students entered the discussion, they first interacted with the interface of the threaded discussion. Most students re-read the instructor's question, and then scrolled through the discussion. Students interacted with those messages from students with whom they could identify. Over time students who integrated themselves at a high level were able to make predictions of the nature of another's message. These students described the posting habits of other students, as well as made assumptions about the contents of their messages. As a result, during the semester, an online learning community was built. An integrated role in the online community is supported by student navigation patterns when students are able to acknowledge another's tone in dialogue (e.g. social presence), and identify with another student culturally. When students navigated the discussion board, the above characteristics are what influenced their feeling of a learning community in that they could connect with another student.

Disagreements also influenced student interactivity and student roles. When controversy took place online, disagreement between learners created an opportunity for others to mediate or oppose another's view. As a result, students were more likely to read and respond, thereby increasing interactivity. However, in the online discussion board, unlike a traditional classroom, not all students witness an argument or disagreement. One student we interviewed, who was segregated in the online discussion, was not aware of the argument. She did not read and respond to many messages, only to a limited few.

The roles that are taken in an online discussion vary. In an online course students are given the opportunity to participate in many threads of the discussion for a broad perspective (integrate themselves), or participate in only a small amount for deeper engagement (segregate). The two experiences are not necessarily mutually exclusive, however, student roles and expectations may facilitate one experience over another.

Students did not respond to all messages that they read. Also known as, 'lurking,' this vicarious interactivity (Sutton, 2001) also supported knowledge building. Those students who identified other student's as 'higher-level' participants, often read those messages to interact with the content. Although students did not always respond in written form, they sometimes printed these messages for future reference.

Finally, all students perceived they learned about diversity and multiple perspectives from the online discussion. Students reported that diversity and multiple perspectives provided the most evidence for learning, which was delivered in the form of feedback in the online discussion.

Conclusion

Bangert-Drowns & Pyke (2001) define learning engagement as the strategic mobilization of cognitive, volition and affective processes to foster personal meaning-making. We will continue to conduct more interviews and observations to investigate the possibilities of cognitive processes (and knowledge building) in terms of message content, volition (decision-making, the student's rationale for reading and responding or not), and affect (the integration of social presence). Some limitations to this particular study include the 'think aloud' process and the protocol for interviewing and observing student participation. Time, as well as other variables, limits the validity of the observation and interview process. However, the observations and interviews also provide insight into online communication for further research with a broader range of disciplines and a revised protocol.

Community and Constructivism: Implicit Pedagogical Models in Virtual Learning

Richard Pountney, School of Education, Sheffield Hallam University, UK
r.p.pountney@shu.ac.uk

Liz Aspden, Learning & Teaching Institute, Sheffield Hallam University, UK
e.j.aspden@shu.ac.uk

Abstract: Communal constructivism attempts to move beyond social constructivism and capture specific elements of the additional value that ICT applications bring to the learning and teaching environment. Case studies of elearning implementations at Sheffield Hallam University are used to examine whether the advent of new educational technologies such as virtual learning environments warrants a new kind of educational theory, or whether they perhaps lure teachers into affordance (Tolmie and Boyle 2000). Properties of one VLE, *Blackboard*, which allow certain actions to be performed and which encourage specific types of behaviour, are examined and the attributes of effective models of online communities of learners are considered.

Introduction

Recent approaches towards teaching practices have seen a shift towards an acceptance of constructivist principles (Dalgarno, 2001). Although constructivism does not represent a single outlook, and is better understood as a continuum (Doolittle, 1999), the various different viewpoints unite around central core beliefs, and stand in stark contrast to behaviourist thinking. Whereas behavioural psychology is associated with an objectivist epistemology, where reliable knowledge about the world exists and can be transmitted from teacher to (passive) learner, constructivists acknowledge the active role of the learner in creating knowledge. So, for example, although cognitive constructivism does believe in the existence of an external reality, it is concerned with the construction of mental structures about this reality, rather than merely a passive assimilation of facts.

Of the different types of constructivism, social constructivism is often perceived as the more holistic viewpoint and, as the name suggests, its epistemological underpinnings emphasise the importance of social context, interaction, and dialogue in knowledge construction. It is these beliefs that Holmes et al have suggested need updating in order to account for the "synergy between more recent advances in information technology...and advances in virtual learning environments" (2001). What they propose is communal constructivism, where students create knowledge not only for themselves, but also for others who are not involved in the initial knowledge construction process. It is suggested that it is the particular attributes of ICTs and VLEs (such as the increased potential for communication, and storage of a variety of data types) that allow this to occur. Rather than passing through the educational system and leaving no trace, students' learning processes and products are available to learners in subsequent years, and potentially to the wider learning community (ie: those not involved in the initial knowledge construction).

Communal constructivism doesn't represent a radical departure from social constructivism in that many of the teaching practices advocated are precisely those that would be used in social constructivist environments. However, where the two do seem to differ is in the scope of influence that students are allowed, and it is suggested that the main interest is in the ways in which "ICTs can be creatively used to bring new life into...diverse ideas" (Holmes et al, 2001). By examining some of the activities taking place across Sheffield Hallam University (SHU), this paper aims to assess the strength of communal constructivism as a theory, as well as asking whether some of the developments could, potentially, be understood in terms of technical affordance.

Technical affordance

The term affordance was coined by J J Gibson (1979/1986), and is a central concept in the approach to perception and action within ecological psychology (Stoffregen, 2000). Behaviour is afforded by the environment, and affordance can be defined as the "properties of the environment of an animal that have consequence for the animal's behaviour" (Stoffregen, 2000). Affordances can be positive or negative and are effected by their context (Barnes, 2000); they are not necessarily deterministic - rather, they are opportunities (Barab et al, 1999, cited in Barnes, 2000) which guide behaviour. In her discussion of affordance of electronic conferencing in relation to distance education, Barnes uses the analogy of a path in the woods to illustrate this - the existence of a path "does not imply that this is the only place we can walk. However, it does provide an easy place to walk as well as providing a direction to walk in" (2000).

This clearly illustrates both the negative and positive aspects of affordance: the path allows the walker to travel more easily through the wood (positive), but may not lead the walker in the direction he wishes to go (negative). It is in this context that we talk about teachers being 'lured' into affordance by the particular attributes of a system: VLEs and ICTs have their own attributes that act in the same way as paths in woods. Email, for example, affords asynchronous communication (one-to-one; one-to-many); the use of electronic conferencing affords closed group discussions to take place online, either asynchronously or synchronously.

In their examination of two contrasting case studies, where CMC has been used to supplement campus based study, Light et al state that the introduction of computer mediated communication "can encourage both tutors and students to examine their existing roles and practices" (2000). In their conclusion, they agree that "As Harasim et al (1995) put it, CMC offers a *customisable* networked learning environment, *tailorable* to a wide range of purposes...even in this medium (and even when they are trying not to) tutors still have a critical role in shaping student learning experiences" (Light et al, 2000). What this paper aims to assess is how much influence the structure of the VLE could have over the individual decisions made by the tutors.

Case study background

As part of ongoing research at Sheffield Hallam University, members of staff who have been using the VLE *Blackboard* have been asked to contribute case studies outlining their use of the available technology, and their motivation behind this. Course tutors were asked to 'self-identify' how the VLE had been used to supplement teaching and learning activities by indicating which of a series of modes of usage could be applied to their course. At one end of the scale are purely content driven sites (or 'support' modes), where the site is used to display copies of essential documents, important dates, contact details for unit leaders, etc. More interactive sites introduce elements of communication (synchronous or asynchronous; one-, two-, or multi-way), assessment (formative or summative; single or multiple attempt), and resource provision, combining these with face-to-face teaching to a lesser or greater degree. The findings from the first phase of case study collection (total of 20 cases collected) have been used to support the conclusions of this paper in relation to the relevance of affordance and communal constructivism, and also to begin identifying attributes of effective online communities.

General findings

Both communal constructivism and technical affordance acknowledge that the availability of ICTs have a profound impact on teaching and learning. For Holmes et al, the emergence of new technologies "force the teacher to undertake a radical reassessment of the way in which they teach" due to the "enormous flexibility" offered (Holmes et al, 2000). This places the emphasis on the decisions made by individuals. The affordance theory, on the other hand, would assume that the availability and adoption of a VLE would guide tutors towards a particular style of teaching. So, the available features would "push behaviour in certain directions" (Tolmie & Boyle, 2000). At a general level, there is little to suggest from the collected case studies that the affordances of the VLE are guiding tutors to adopt practices that they would not necessarily wish to use. In fact, there was a strong sense of variety, with tutors choosing to adopt styles of site organisation that fitted in to their personal view of teaching and learning: there was no wholesale, widespread adoption of a particular feature, or set of features. Additionally, there are instances of tutors actively reassessing the practices they have adopted, rather than continuing in any particular way. These findings seem to assert the strength of the individual in the decision making process, and the following section outlines some general observations that support this, as well as providing a more in depth look at three undergraduate units.

Discussion

Barnes suggests that "The main issue concerning affordances of ICT and education is how and when ICT is an appropriate medium that enhances the learning process or learning outcomes" (2000). Comments from tutors at SHU such as "ICT is used alongside teaching, rather than being the driving force" were common, showing that they were interested in using particular functions to support their own aims. Appropriate use of the features of the VLE, and awareness of the need for this, has been highlighted throughout the case studies with tutors actively selecting - and amending their use of - particular features. So, for example, we can examine one affordance of the VLE - the potential for multi-way communication to occur - and compare three different units, all of which have tried to introduce some element of this. In the first case, the synchronous discussions proved extremely successful, leading to the conclusion that online communal learning has the potential to work well at undergraduate level. In the second case, the synchronous communication was not used ("if the students are on campus at the same time anyway, it makes more sense for them to be together in a 'physical' environment"; quote taken from case study), but the asynchronous discussion area has been used extremely effectively. This has been done to the extent that it has fostered a sense of community, with students happy to share thoughts and ideas in this environment. In the third case however, where the students were all professionals in full time work, the use of secure Discussion Boards for asynchronous communication is being discontinued. It is felt that "the commitments of a full time job and study leave little time for engaging in what is perceived as non-essential dialogue" (quote taken from case study). This pattern suggests that, even if tutors are being led down a particular path by the availability of certain functions, they are tailoring their use of the VLE to their own ideas, and the needs of the students: it supports the assertion of Light et al (2000) that "there is not *one* way, or even perhaps a *best* way of using CMC to support student learning".

We will now turn to a more descriptive look at three undergraduate case studies. The first of these - *ICT in an Educational Context* - is a specialist, level 3 unit taught over 7 weeks. In a previous paper (Pountney et al 2002), the manifestation of the nine critical elements of situated learning contexts as identified by Herrington & Oliver (see Herrington & Oliver, 2000) was examined, with the conclusion that it provided a highly effective environment for social constructivist learning activities: It provided authentic contexts and activities, alongside access to expert thinking and different perspectives; the environment allowed students to collaborate in knowledge construction, to reflect on their work, and to articulate their beliefs; it allowed for the integration of authentic assessment, and for the teacher to provide scaffolding at critical times. In looking at whether it could be re-described in terms of communal constructivism, the authors remained sceptical, and whilst acknowledging that communal constructivism does provide a useful framework for ensuring that networked learning is appropriately employed, they felt that it did not depart radically enough from social constructivism to warrant being a new educational theory (Pountney et al, 2002).

One of the fundamental tenets of communal constructivism is students developing a body of knowledge that will potentially benefit other learners, and teachers, thereby allowing the students to leave their mark on the course. By examining a second case study, where undergraduate students are involved in collecting fieldwork relating to tourism in the City of Sheffield, we can find support for the Holmes et al's belief that "the synergy between the more recent advances in information technology...and advances in virtual learning environments" (Holmes et al, 2001) does allow new educational opportunities. The information collected by the students in one year is stored in a hierarchical database, which has been packaged within *Blackboard*. This allows students in subsequent years to access and use this data alongside their own to map longitudinal changes in tourism provision. So alongside the authentic contexts already provided by the unit (eg: use of fieldwork, and collection of data reflecting how information is used in real life), it could be argued that the particular use of ICTs in this unit enable an additional layer of authenticity to be added to the learning process, as students can see how knowledge created at one point in time can be used in the long term, by others, as it would be in industry, for example.

Communal constructivism also argues that students can be "actively involved in creating knowledge that will benefit other students" (Holmes et al, 2001), an idea that is echoed in the development of a body of knowledge to be used over time. In our final case study we look at an instance that supports the idea of students collaborating, and creating knowledge for themselves and others, in a way supported specifically by the use of the VLE. Second year undergraduate students have been demonstrating high levels of engagement with the networked learning opportunities afforded by the *Blackboard*. This has been particularly well demonstrated in the use of the Discussion Board, where they have regularly been posting thoughtful messages, including suggestions for useful resources that they have found outside of the scope of those suggested. One point is particularly relevant here in relation to communal constructivism: although students could just as easily communicate, collaborate and pass on information on a one-to-one basis, or within controlled groups, the exchanges and processes could potentially remain invisible to the tutor. However, within the secure environment offered by the VLE, the students feel comfortable sharing their ideas within the whole group, and the elements of the collaboration are made visible to the tutor as well as to other students who may potentially have been excluded from individual exchanges. Thus, it could be argued that the particular features of the VLE allow these exchanges to be made available to a wider community.

The above three case studies illustrate units where the pedagogic strategies employed have created effective online communities of learners. A possible interpretation of this is that the particular features of the VLE have encouraged particular types of behaviour. The availability of multi-way communication, and the ability to store data, might have prompted tutors to use these facilities to supplement their learning and teaching strategies simply because they were there: they might have provided a particular path through the woods. Where the affordances have proved successful, they have been developed and integrated to supplement the teaching in effective ways. However, as in the instance mentioned briefly above, wh ere they have been felt to be negative or unnecessary, they have been reassessed and their use discontinued.

Conclusion

It is apparent that the opportunities offered by ICTs do provide the opportunity for tutors to actively reassess their teaching practices, and it could equally be suggested that the availability of certain features do suggest particular strategies. However, to argue that it is the facilities themselves that push behaviour in certain directions is to ignore the role of the tutor - and the students - in the process of developing the course. In the cases collected at SHU the positive (or not) engagement of students and tutors with the technology has as strong an influence over the development of the course as does the availability of certain features. Tutors are actively involved in the decisions made about the course, rather than being just passively guided by the opportunities offered by the technology.

Abstract: This paper presents a scheme for improving an efficiency of image retrieval systems. The image indexing and retrieval technique based on the combination of the autocorrelogram method and color difference correlograms method is proposed. Color filtering technique is used for quantization of the RGB colorspace into 64 colors to reduce the complexity and calculation time. Then, both color and spatial information are employed to build the index of each image by using autocorrelgram and color difference correlogram. The distance measure technique is used to retrieve target images from the database. Experimental results suggest that this method can index and retrieve images which different views of the same scene, large changes in appearance. The performance of the image retrieval system is also improved significantly when compared with both color histogram and color correlogram method.

Introduction

Content-based image retrieval system is one of the popular techniques for retrieving image from image databases. There are two steps that are common used in most image database information retrieval systems as followings: indexing and searching (Huang et al., 1997). In indexing process, each image in a database, a feature vector capturing certain essential properties of the image is computed and stored in a feature-base. Then, in searching process, given a query image, its feature vector is computed, compared to the feature vectors in the feature-base, and images most similar to the query image are returned to the user. In a content-based image retrieval system, color (John et al. 1995, Swain 1991), the most recognizable element among image contents, is usually used for various image database applications. Color histogram, however, does not provide enough spatial information such that different images may have similar color histogram. To handle the weakness of color histograms several new features that strive to integrate both color and spatial information have been proposed (Huang et al., Pass et al., Markus et al., Hsu et al.)

This paper proposes a scheme that makes use of both color and spatial information for the image indexing and retrieval system. The effectiveness of the proposed scheme is confirmed by the experimental results and compared with both color histogram and color correlogram method.

Image Indexing Scheme

The process consists of three steps namely: color filtering, autocorrelogram (AC) and Color different correlogram (CDC).

1. Color Filtering

The process is used for quantization of the RGB colorspace of each image into 64 colors to reduce the complexity and calculation time in the following processes.

2. Autocorrelogram

A color correlogram expresses how the spatial correlation of color changes with distance [1] and is defined by the formula shown in Eq. 1 and Eq. 2.

Let I be an $n \times n$ image. The colors in I are quantized into m colors $c_1, \ldots, c_m$. $H_c(I)$ is number of pixels of color c_i in I. For a pixel $p = (x,y) \in I$, let $C(p)$ denote its color. Lets $I_c = \{p \mid C(p) = c\}$.The distance between 2 pixels, i.e., for pixels $p_1 = (x_1, y_1)$, $p_2 = (x_2, y_2)$, defined $|p_1 - p_2| = max\{|x_1 - x_2|, |y_1 - y_2|\}$, let [n] denote the set {1, 2, ..., n}. Let a distance d ∈ [n] be fixed a priori. i,j ∈ [m], and k ∈ [d].

$$\gamma^{(k)}_{c_i,c_j}(I) \cong \Pr_{p_1 \in I_{c_i}, p_2 \in I}[p_2 \in I_{c_j} \,\|\, p_1 - p_2| = k] \quad (1)$$

$$\gamma^{(k)}_{c_i,c_j}(I) \cong \frac{\Gamma^{(k)}_{c_i,c_j}(I)}{H_{c_i} x\, 8k} \quad (2)$$

The autocorrelogram captures spatial correlation between identical colors only and defined by Eq. 3.

$$\alpha^{(k)}_{c_i}(I) \cong \gamma^{(k)}_{c,c}(I) \quad (3)$$

3. *Color Difference Correlogram*

Color difference correlogram (CDC) is the scheme that is modified from the texture description technique (Robert et al., Manjunath et al., Randy, Nepal et al.). Color difference correlogram of an image is graph or table that indexed by color difference value, where the k-th entry for $Diff_i$ specifies the probability of finding color difference value $Diff_i$ of pixels at distance k from any pixels in image. The color difference value between two pixels having distance equal to k is defined by Eq. 4.

$$Diff_i = |\, C(p1) - C(p2) \,| \qquad \text{where } |\, p_1 - p_2 \,| = k \quad (4)$$

The color difference correlogram is calculated by the formula in Eq. 5.

$$Cdf^{k}_{diff_i}(I) \cong \Pr_{p_1,p_2 \in I}[\,|\, C(p_1) - C(p_2) \,| = diff_i \,\|\, p_1 - p_2 \,| = k\,] \quad (5)$$

$$Cdf^{k}_{diff_i}(I) = \frac{\beta^{k}_{diff_i}(I)}{n_1 x n_2 x\, 8k}$$

Image Retrieval Scheme

The process is used to retrieve images from the image database. The technique of distance measure (Huang et al., 1997) is employed in the process. This paper use d_1 distance measure for comparing histogram, autocorrelogram, color difference correlogram, and AC/CDC because it is "relative" measure of distance.

d_1 distance measure for histogram, autocorrelogram, color difference correlogram and AC/CDC is defined by Eq. 6 to 9.

$$d_1(h) = |\, I - I' \,|_{h,d_1} \cong \sum_{i \in [m]} \frac{|\, h_{c_i}(I) - h_{c_i}(I') \,|}{1 + h_{c_i}(I) + h_{c_i}(I')} \quad (6)$$

$$d_1(\gamma) = |\, I - I' \,|_{\gamma,d_1} \cong \sum_{i,j \in [m], k \in [d]} \frac{|\, h_{c_i}(I) - h_{c_i}(I') \,|}{1 + h_{c_i}(I) + h_{c_i}(I')} \quad (7)$$

$$d_1(CDC) = |\, I - I' \,|_{CDC,d_1} \cong \sum_{diff_i \in [diff], k \in [d]} \frac{|\, CDC^{k}_{diff_i}(I) - CDC^{k}_{diff_i}(I') \,|}{1 + CDC^{k}_{diff_i}(I) + CDC^{k}_{diff_i}(I')} \quad (8)$$

$$d_1(\gamma, CDC) = d_1(\gamma) + d_1(CDC) \quad (9)$$

Performance Measures

The performance of the scheme is measured by using the parameters the same as described in (Huang et al.,

1997) as follows.

$$r-measure = \sum_{i=1}^{q} rank(Q_i') \tag{10}$$

$$Avg\ \text{r - measure} = \frac{\text{r - measure}}{q} \tag{11}$$

$$p_1-measure = \frac{1}{\sum_{i=1}^{q} rank(Q_i')} \tag{12}$$

$$Avg\ \text{p}_1\text{ - measure} = \frac{\text{p}_1\text{ - measure}}{q} \tag{13}$$

Experiment Results and Conclusion

The proposed scheme is implemented by using Visual Basic version 6.0 and Microsoft Access Database. The experimental image database is a heterogeneous image database. It consists of 10,204 images in varieties formats such as JPEG, BMP and GIF and varieties sizes. The number of color in each image is quantized into 64 colors. Thus, color difference of 64 values are computed, set {0, 1, ..., 63}. The distance measure is performed by d={1}, d={1,3}, d={1,3,5}, ..., d = {1, 3, 5, 7, 9, 11, 13, 15, 17, 19}.

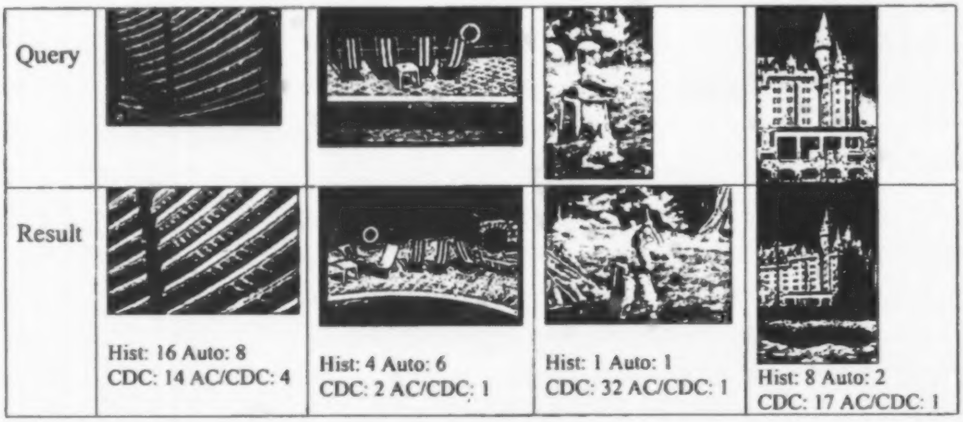

Figure 1. Sample queries and answers.

For the performance evaluation, one hundred queries, each with a unique correct answer, are used in the experiment. Figure 1 shows sample of some queries, query results and ranking of the result in various method namely: color histogram (Hist), autocorrelogram (Auto), color difference correlogram (CDC) and autocorrelogram and color difference correlogram (AC/CDC) methods. It can be seen that the AC/CDC scheme performs better performance than the other compared schemes. The scheme can also retrieve images with different views of the same scene, large changes in appearance.

The performance of the proposed scheme is also compared with other methods, color histogram, autocorrelogram and color difference correlogram. The comparison of average r-measure values and average p1-measure for each method are shown in Figure 2 and 3, respectively. From the experimental results, it could be concluded that the use of autocorrelogram and color difference correlogram for indexing and image retrieval that could improve the performance of the image retrieval system.

Selecting a Course Authoring System

Dr. Robert V. Price, College of Education, Texas Tech University
Bob.Price@ttu.edu

Abstract

Selecting a Course Authoring Tool (such as WebCT or Blackboard) that best meets the needs of the course author or instructor is an important consideration in creating quality online instruction. This paper reviews the features and considerations which course authors and instructors should consider when selecting a course authoring tool. An evaluation rubric is presented which those evaluating course authoring tools may use to guide them in their selection of the most appropriate system for the intended use. The rubric includes features common to course authoring tools, a rating scale of their ease of use, and a rating scale for the relative importance of each feature to the course author.

Providing course materials and information through the Web is a new frontier for many educators. *Course authoring tools* (CATs) are vital for the development and maintenance of course Web sites. A CAT is a computer program that is used by a course developer to design, develop, and maintain learner based web sites. Course authoring tools such as *WebCT* and *Blackboard* provide designers the means to distribute course materials, content, and tests to learners through the Internet. These tools use program components that allow course designers to design and deliver courses online, provide course material updates, and effectively deliver instructional modules to learners through standard web browsers.

The use of course authoring software for developing and maintaining courses has become a necessity. Course issues are important because they determine which course authoring tool is best suited for the job at hand. Selection of an authoring tool will have a direct affect on course development and the achievement of program goals.

Features of Course Authoring Tools

The selection of a course authoring software program is simplified if the user is aware of the features needed for course development. The software features considered here include course development, course collaboration, and course management (Gray, 1998). These software feature categories stem from typical activities that occur in the instructional environment and are shown in Figure1.

Course Development	Course Collaboration	Course Management
Content: lectures, materials and homework are developed for delivery through the web. Delivery: course development is conducted to include content. Forms of delivery include text, HTML, video, animation, and audio.	Access: course materials are accessed through learners' Internet service providers. Interaction: learners interact using own Web browsers. Support for e-mail, document sharing, learner homepages, discussions, etc.	Assessment/Feedback/ Administrative: grade books, quizzes, exams, course related reports, course security, and software support.

Figure 1: Class activities that fall under software tool features (Aggarwal, 2000)

Tools for Course Development

Some features to consider for course design include:

- Site search tools,
- Course participant homepages, and
- Course development (templates).

Search tools help learners find useful information they need. Search tools can be invaluable for prospective learners who may be interested in online course offerings. *Learner homepages* are one way to help learners get to know each other. Learner home pages help because they allow the participants a chance to share personal information and interests. They provide learners with opportunities to help reduce the psychological effects produced by the distance between them.

A *course-authoring template* allows the developer to construct an online course using a pre-designed format. Templates are easy to apply to specific course development applications and adapt to changing situations. Templates help a designer get a new course up and running in the shortest amount of time possible. When a designer has a custom course template, it can be shared among divisions or departments to provide standard course interfaces and visual consistencies. The ability to develop and distribute a custom template design will help an organization accomplish this task.

Tools for Course Collaboration

Some of the main tools provided for course collaboration are:

- Chat rooms,
- Message boards,
- E-mail for course participants,
- Whiteboards support, and
- Special workgroup features.

Course discussions may be conducted either asynchronously or synchronously. Asynchronous discussions are usually threaded and allow learners to respond when it is convenient. This type of discussion typically takes place over several days, or longer, for each topic. Synchronous, or real-time discussions, allow learners to participate in a virtual classroom session and communicate to others who are logged on at the same time. Instructors can designate a specific time for discussions or workgroup activities.

Electronic bulletin boards allow course instructors to post announcements related to the course that learners can visit periodically to check for new information. E-mail provided through course management programs gives learners private e-mail accounts that are specific only to the courses for which they are enrolled. E-mail is very useful for receiving course assignments and corresponding with learners on an individual basis. Some instructors prefer web based private mail to regular email because it eliminates the need to maintain a class email list, and the problems that may be associated with learners working from a variety of ISPs.

Whiteboards allow the instructor to provide course participants with visual information (i.e., computer graphics) from the computer or a physical whiteboard (i.e., drawings). Instructors can use whiteboards to enhance synchronous discussions.

Finally, web-based *workgroup features* can help provide collaborative elements to learners. This is done through a special workgroup option that provides group members with web-based resources that might include a workgroup homepage, a private discussion area, or file transfer options for the workgroup.

Tools for Course Management

Some features to consider for managing a course include:

- Course grade books,
- Assessment tools (such as quizzes and exams),
- Course access control,
- Software support, and
- Course related reports.

Web-based course *grade books* provide a means for grading and tracking learner progress. Some course authoring tools provide tests, grade books, and other data handling options. Assessment tools provide a variety of options to the course instructor, such as, the ability to generate standard or random tests and quizzes for online assessment. Grading and other forms of feedback can be provided immediately to learners, if desired.

Course access control provides a means to secure course sites and learner access. Course authoring software should provide for course sites that are easy to access by authorized users, yet guard against unauthorized use. The most common methods of access control are user names and passwords.

Learner tracking features provide the ability to generate various reports concerning learner activities in a course and the use of online course resources. Such reports help instructors and designers evaluate the effectiveness of course delivery and design, and help instructors evaluate learner participation.

Evaluating Course Authoring Programs

There is no one best program which is best for all situations. The various software features discussed previously will vary in importance to individual course authors. While many tool features are common to most software programs, the quality of these varies from one program to another. The rubric below is provided as a framework for evaluating course authoring software. Course authors and designers could use this tool to help select the authoring tool that will work best for their needs.

Authoring Software Tool Evaluation Rubric

Program Title:	Version:
Publisher:	Price:
Reviewer:	Date:

Tools for Course Development:	**Importance Rating 0-4**	**Quality Rating 0-4**	**Score 0-16**
Site Search Tools			
Participant Homepages			
Course Development Features			
Ready-Made Templates			
Custom Templates			
Quick Start Features			
Tools for Collaboration:			
Synchronous Chat Capability			
Message Board			
Private E-Mail Capabilities			
Whiteboard Capabilities			
Workgroup Capabilities			
Tools for Course Management			
Course Grade Book			
Assessment Tools			
Course Site Security			
Course Reports			
Student Progress			
Site Resource Use			
Course Evaluation			
Software Support			
Total Score			

Figure 2: Authoring Software Evaluation Rubric

The rubric lists the primary features of authoring programs. To use the rubric, the reviewer should first decide how important the features listed are to them. Using the following scale, enter a number from 0 to 4 for each listed tool. If there are other important tools which are not listed, they can be added to this form.

0 = Not Important
1= Minor Importance
2= Some Importance
3=Very Important
4=Extremely Important

After rating the importance of the tools, review the actual authoring software program or a demonstration version of it and enter your assessment of the quality of each tool using the scale below from 0-4. Consider ease of use, power, and flexibility in your assessment.

0= poor quality or not available
1= Weak
2= Fair
3=Good
4=Excellent

After evaluating the features of a software program, multiply your **Importance Rating** by the **Quality Rating** and enter the result in the **Score** for each tool. Tools which are rated 0 in importance will receive a 0 regardless of the quality rating so the reviewer can pay little attention to these tools. Either lower importance ratings or lower quality ratings will cause the score for a tool to be low. The highest overall ratings will result from those tool features which have ratings of both high importance and high quality. After evaluating all of the features of an authoring tool program, total scores for each item can be totaled by adding up the scores of all the tools and entering the result in the **Total Score** cell. After reviewing all of the authoring software programs available or reviewing those selected for further indebt consideration, the total scores and individual scores can be compared and a final selection made.

Use of this evaluation rubric forces reviewers to decide which features are important to them as well as providing a framework for evaluating the features of the programs being considered. This tool could be used by a selection committee or by individual designers or instructors to help them select the authoring tool which is most likely to meet their needs.

Conclusion

Use of this evaluation rubric by course designers will help them evaluate the course authoring tool options available to them and to select a tool which will work best for their unique needs.

Building Worldwide Mentoring Tools: Content Analysis of Visited Web Page and Matching

W. Curtiss Priest, Ph.D., Director, Center for Information, Technology & Society
Jared Luxenberg, Center Fellow
August 21, 2002

Abstract

Peer-to-Peer (P2P) Communications has become increasingly more recognized as a powerful tool for learning. In a project supported by Cisco Academies we have designed, built and are testing a new tool for P2P. We wished to have online mentors matched to online learners, but, the problems of successful matching, taking into account the current interests of the learner is challenging. Our design is to: 1. Give K-12 learners web-based learning resources 2. The student has a hover button that tracks their journey and says "Find me a Mentor" 3. They press that buttons: a. The contents of the currently visited web page is read b. We interpret the key concepts or topics of the visited page c. We employ a sophisticated matching tool (like the "find similar" for web pages at Google) to get a ranked list of relevant mentors d. Using an intermediate server, we find which of these mentors are online e. We make the match within seconds and place the learner in touch with the mentor via IM

Background

Mentor-Matcher is a knowledge sharing tool. To grasp how it performs knowledge sharing, it is useful to put this tool in perspective of other knowledge sharing tools. Once it is defined in those contexts, the technique for constructing the tool is addressed, followed by how it is currently being piloted.

The history of computer-based knowledge sharing tools goes back to the creation of online databases, such as by Lockheed Dialog, which terminals could connect to via packet networks in the early 70's.

Also created in the early '70's was a knowledge sharing tool called EIES by Murray Turoff at the Stevens Institute of Technology. Called computer teleconferencing, this tool and others like it permitted an asynchronous dialog among a group of participants where, again, using a dial-up terminal, users could dial to a central computer and post notes to a set of discussion topics.

Quite separately, on the UNIX side of computing, a hodgepodge of "news feeds" were created called Usenet. Either using telephone connectivity, directly, or by obtaining a "feed" from a computer networked to other computers, the user would receive a stream of messages sent to the "group" on the local machine. The user could either reply to a message (called threading) or open a new subject of discussion by announcing it in the subject line of the message.

Yet another mode of knowledge sharing was the Bulletin Board System (BBS). Here permanent messages could be posted in "Forums" and some of the first online chat sessions and chat rooms were created using software such as PCBoard. Other knowledge sharing occurred through the exchange of freeware and shareware files, also placed under topic headings (or directories).

In the '80s, with the prevalence of the PC, it was now possible to distribute knowledge sharing systems – a form of communications which in the '90s was called Peer-to-Peer communications (P2P).

This author developed (and patented) the first P2P knowledge sharing system that combined e-mail communications, a knowledge database, and a topic structure. A topic structure (or controlled vocabulary) need be thought of as no more than a set of directories containing messages sent in the "context" of the topic.

A later implementation of such a P2P knowledge sharing system was Microsoft's Outlook which permitted the user to exchange information within "categories." Like the Priest implementation, both the category and the information were bundled into a header, a header different from a typical e-mail header.

With the advent of the Internet (net), a wholly different form of knowledge sharing grew, which actually resembled the original online database format more than later P2P implementations.

The net permitted thousands of different sites to flourish, and each contained knowledge of one kind or another. Early pioneers such as Yahoo and Lycos saw the need to comb these sites for information and provide a portal to an index of this information via web-based search engines. The technique behind the scene was the "webcrawler" which gathered words from site after site, stuffing them into a single searchable index. So these tools resembled the early text database tools of the '70s except that the "databases" were much more widely distributed.

On the net, the BBS chat rooms gave way, first to IRC (Internet Relay Chat) and then to P2P chat such as AOL Instant Messenger.

Mentor-Matcher Design

In a prior project we had designed a desktop agent (Tracker) that followed K-12 students using the web for learning resources. In that 81% of a student's time is spent outside of school (P. Kenneth Komoski, "The 81 Percent Solution," *Education Week*, January 26, 1994, p. 52), the goal was to provide a way to encourage learners to use the net to learn more. And, hopefully, the more passive activity of watching around six hours of television a day might be reduced and replaced with something more constructive.

A learning resource portal site was constructed (http://www.eLearningSpace.org aka eLs) with support from the U.S. Department of Education. Students receive a "learning credit" for each hour spent learning at some 4000 identified resource sites and can exchange those credits for donated goods (such as brand name shoes, etc.) via an online auction site (much like eBay).

Cisco Academies showed interest in this work and have been constructing the backbone of a knowledge sharing system for the 8000 or so academy sites around the world. We suggested that the time was right to combine knowledge sharing tools in a way that merged the abilities of web-based search engines and instant messaging.

The design problem was "how to elicit mentoring strengths of online mentors and match those abilities with the current learning needs of the learners "

The national standards efforts had produced a set of topics and sub-topics in the area of math, science, and reading. So, using Javascript we built a topic/sub-topic list where sub-topics and sub-sub-topics can be display by clicking on a plus sign next to the higher topic – a technique used in Acrobat and other indexed lists.

This approach works well because mentors have a well defined set of strengths that do not change much over time. However, a student's learning interest changes by the hour.

Somehow we needed to make a match between a topically defined person – the mentor, and a learner who is selecting and viewing web resources.

This problem is similar to the web search engine problem of finding web pages similar to the currently viewed web page. Ah, but the mentor topics were stored in a database; how to make these behave like web pages?

To solve this problem we create a set of local web pages with a key for each page back to each mentor. But how to populate the pages with lots of words?

Since several encyclopedias are online, we could build a tool that "expanded" a knowledge topic – say "planets" – into a web page of up to 30,000 words discussing planets. To do this we built an intermediate tool called "WordScooper."

After the mentor signs on to the project and provides a set of topics and/or sub-topics, the server immediately has WordScooper query Microsoft's Encarta for words on that subject. We created rules where WordScooper behaves a bit like a webcrawler, taking words from various levels of encyclopedia pages by following the links on the top page. We ignore pages that are not subordinate to the top web page.

So, now we have reduced the design problem to trying to match the learner's currently viewed web page (an indicator of their knowledge needs) with our locally stored set of web pages (which are keyed back to the mentors).

Knowing that there are several dozen web search engines and that many of these are available in several ways to search one's own web pages, we went to http://kresch.com/search/search.htm which lists all known search engines and their features. While the feature of "find similar" was **not** in their summary of features, they **did** have active links to sample sites employing the particular engine. Using this we reduced the list to four possibilities. Of these, the engine by Thunderstone (Webinator) appeared to be widely used by colleges and universities and, best of all, one could obtain the search engine software and run it under the local server's OS (in our case NT5). This is free, provided the server can access the Thunderstone site to receive authorization to run. [Alternatively, the entire text-based, SQL featured search engine (called Texis) can be purchased for $11,000 (U.S.).]

The matching and messaging process operates as this: 1.) Webinator is instructed to bring down the web page currently viewed by the learner and convert the page to plain text; 2.) Webinator is instructed to use its "metamorph" facility to create an internal set of thirty frequent and unique words which define the content of the web page; 3.) a search engine query is submitted with that list, searching all of our local web pages of mentor-related word-expanded topics; 4.) a rank order list of relevant mentors is returned; 5.) an intermediate server of ours determines which mentors are currently online, and displays a list to the learner of online mentors and the word that caused the match – each item in the list is a "link" to each online mentor; 6.) the learner clicks on one of the links; our online AOL-IM-like server sends a message to the mentor including the student's name and a display of the URL the student is currently viewing; the mentor may accept or refuse the "assignment;" if he "yes"," our intermediate server sends a message of acceptance to the learner and a two-way chat occurs; 7.) we log the entire chat session and its duration so that the learner can receive learning credits (as above) by verifying that the sites are on the list of educational web pages approved by eLs and logging the minutes in the student's eLs portfolio. The data gained by tracking the student's web browsing had to be detailed (keystrokes, etc.) and be in a form that was easily accessible from ASP scripts.

In first researching tools, we wished to use client side Javascript to track web browsing. This approach presented some control issues. Netscape would not allow tracking outside of the domain the Javascript page was hosted on, and some of the features of the script did not work properly in Internet Explorer (IE). Since Javascript implementations vary from browser to browser, and some users have Javascript turned off, this solution was not feasible. We looked for other ways to track web surfing. We looked at server-side solutions, such as a backwards proxy, but the overhead associated with these out weighed their benefits. We eventually found a way to automate IE on the client side, eliminating the need to run Internet traffic through a central server.

Microsoft provides an ActiveX interface to launch an instance of IE. Events are fired when the user visits URLs, closes the window, reloads the page, etc. This allows total control over the browser, and it provided the degree of control we needed.[*]

The field test stage has begun, and the tool has met and exceeded all expectations for performance.

In summary, the project illustrates a useful way to combine two different ways of accessing knowledge: 1.) use of keywords or a controlled vocabulary, and 2.) full-text searches. The choice of one and/or the other relates to the ability or inability to use a controlled vocabulary as pieces of this design problem have demonstrated..

---

[*] The authors express their concern that "all roads" seem to lead to IE and await the U.S. Justice Department suit results against Microsoft in this regard.

Using Animated Pedagogical Agents to Teach Entomology

Abstract: Animation technologies are widely used in the areas of entertainment, such as video games. Animation technologies have also been implemented in education in the form of animated pedagogical agents (Johnson, 2001). In this paper, animated pedagogical agents are used as teachers in an introductory level CD-ROM based Entomology course at Auburn University. The designed course is self sufficient, as the animated teachers go through the lectures, provide quizzes and communicate verbally with the students. This new CD-ROM based course has several advantages, such as inspiring, attractive, flexible, cost saving and students evaluated this course to be very effective as teaching tool.

Introduction

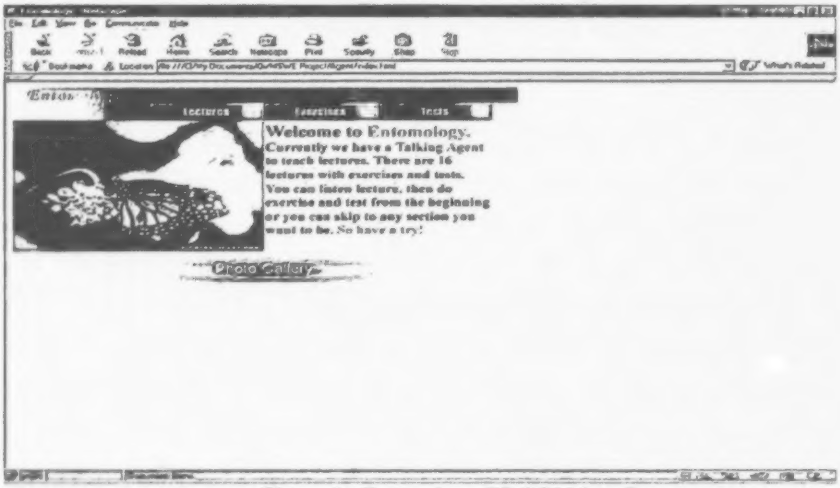
The CD-ROM Entomology course, figure 1 is based on Entomology 2044 – An Introduction to the Study of Insects. This course is an independent study course created by Dr. J. Wayne Brewer, Professor in the Department of Entomology at Auburn University. This course consists of sixteen lessons contained in a course book and a series of videos. Each lesson includes a reading assignment in the required textbook, a set of lesson objectives, a written lecture on the assigned subject, written exercises to be submitted for grading and a set of practice test questions. The completed lessons, quizzes and exams are submitted to the instructor through the Auburn University Distance Learning Center for grading. From September 2001, the authors worked together to redesign the original Entomology course to one CD-ROM course. In this new course, there is an animated pedagogical agent (Johnson, 2001) who represents the traditional instructor. The agent addresses the lecture, provides quizzes and corrects practical test questions instead of a human teacher. All course contents are on one CD-ROM, which will be delivered to the students by the Auburn University Distance Learning Center. The CD-ROM course has the following advantages:

1. More inspiring - Instructor can add any inspiring contents, like questions, quizzes easily as compared with video tapes traditionally used for distance learning courses.
2. Attractive – Teaching by agents (animated teachers) can be fun for students if designed appropriately.
3. Flexible - Students can design their own learning process based on the necessary requirements.
4. Feedback - Educator can communicate with students easily and in time. All feedback can be processed quickly and precisely.

5. Cost saving – Educator and students can save money on tedious video recording, shipping or mailing.

However, there are also some limitations on this new CD-ROM course design:

1. Text-speaking technique – Though the text-speaking technique has improved, it can not compare with the real human voice.
2. Third party developer - Educators or students need a third party for the agent development, such as multimedia specialists.
3. The basic requirement for students –The student should have a computer with necessary support system together with the working knowledge of simple computer operations.



Welcome to Entomology.
Currently we have a Talking Agent to teach lectures. There are 16 lectures with exercises and tests. You can listen lecture, then do exercise and test from the beginning or you can skip to any section you want to be. So have a try!

Figure 1: Entomology CD-ROM Interface

In the following section, the implementation, architecture and importance of the proposed CD-ROM course will be discussed.

Implementation

The Entomology course is implemented using JavaScript, HTML and a third party plugin. All contents are on one CD-ROM. When the student inserts the CD into a Windows computer, the application runs automatically .

Haptek Plugin

This project was built using the Haptek VirtualFriend 4.1 plugin, which is available as a free download from the Haptek website (Tech News – Haptek.com, 2002). JavaScript is used to control the VirtualFriend plugin. The core channel of communication with the plugin is a function called *SendText()*. *SendText()* simply sends a string of text to the plugin. If the string is simple text then the VirtualFriend will speak the text via speech synthesis. However, the VirtualFriend has a set of special commands that can be embedded in any sentence used to control the plugin, these commands are called Haptek Hypertext. The Haptek Hypertext commands can direct the plugin to download a new texture, perform an animation sequence, morph, or even load an entire new scene. For convenience, most of the Haptek Hypertext commands have been encapsulated in a set of easy to use JavaScript functions.

Architecture

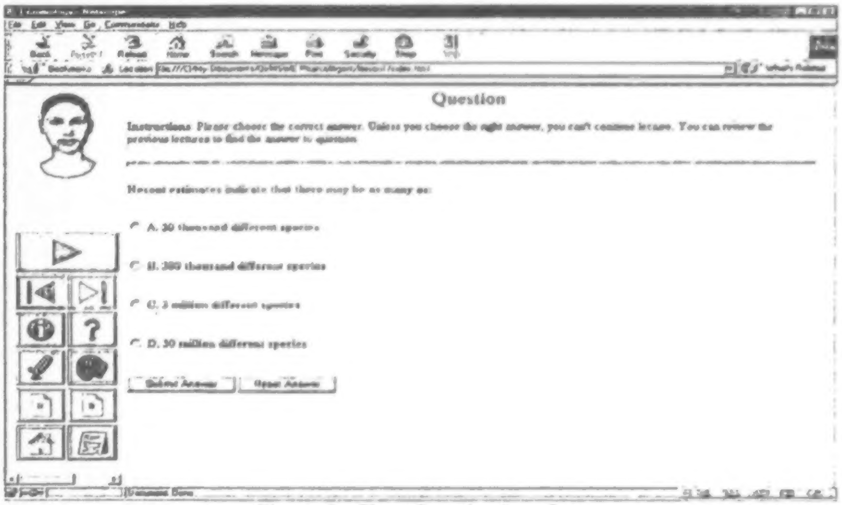
The physical architecture of the CD-ROM entomology course begins with a root directory. The root directory contains images, software needed such as Microsoft Speech API, Microsoft TTS Engine

BEST COPY AVAILABLE

(Tech News – Microsoft.com, 2001), Haptek Plugin, Cygwin and three subdirectories – Agent, NoAgent and Animation directories. Considering some computers may not have the minimum system requirements, there is a version of course without the Agent in the NoAgent directory.

In the Agent version, an animated teacher goes through the lectures, provides quizzes and communicates with the students verbally. The No-Agent version presents the same content and explanations as the Agent version but the Agent is not present. The Entomology course interface is organized into four sections: Lectures, Exercises, Tests and a Photo Gallery, which is shown on Figure 1.

There are sixteen lessons in total. Students can access each lesson by clicking the corresponding link. Each lesson's interface consists of two frames: Navigation frame (left) and Content frame (right). In the navigation frame, there is one animated instructor and several function icons. Students can control the agent's speaking, choose different lessons, and skip to exercise or test sections by clicking the function icons. To help students master the content easily and fast, the content is divided into small concepts. Each concept is further subdivided into many small scenes so that agent can speak sentence by sentence. Between each concept there is a short question related to the previous concept. Students are required to correctly answer the short question. If the student can not answers the question correctly, he/she will not be permitted to proceed to the next concept in the lecture. Students can go back to the previous concepts to find answers. Figure 2 shows the lesson interface with the short question.



Question

Instructions: Please choose the correct answer. Unless you choose the right answer, you can't continue lecture. You can review the previous lectures to find the answer to question.

Recent estimates indicate that there may be as many as:

○ A. 30 thousand different species

○ B. 300 thousand different species

○ C. 3 million different species

○ D. 30 million different species

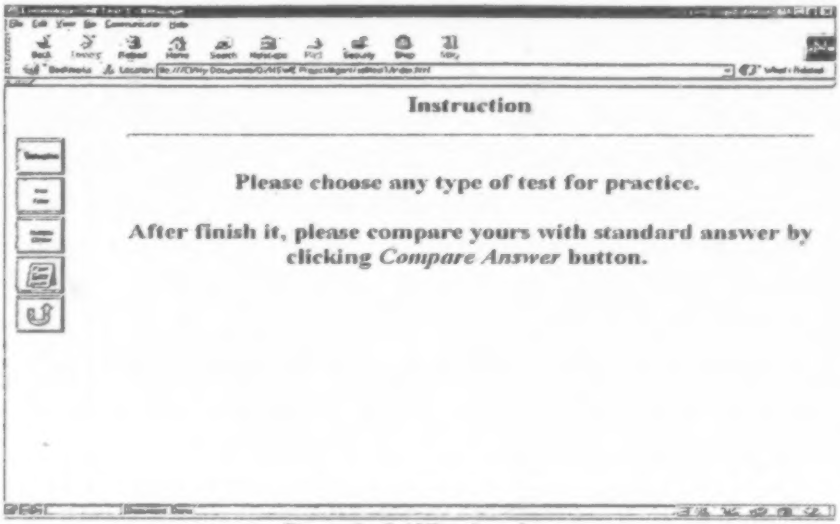
Figure 2: Short Question Interface

There are also sixteen written exercises in total. Each exercise is related to each lecture and includes three parts: definition responses, discussion responses and short question responses. Students can check their answers for correctness by clicking on the "compare answer" icon. In the navigation frame there are six icons: *Introduction*: is linked with an HTML page to explain the exercise section. *Definition responses*: is linked with an HTML page to show some terms needed to be defined. *Discussion responses*: is linked with an HTML page to show some discussion questions to be answered. *Short question responses*: is linked with an HTML page to show ten short questions and after students fill all the blanks they can click the compare answer button leading to a pop up dialogue box showing the percentage of correct answers. *Menu*: by clicking this icon the current exercise interface switches to an exercise list interface so that the student can choose different exercises from the links. *Back*: by clicking this, the current exercise interface switches to the lesson interface.

There are also sixteen self tests in total, each test is related to each lecture or written exercise and includes two parts: *multiple choice* and *true-false*. Students can compare their answers with standard answers after they finish any of two parts. In the navigation frame there are five function icons: *Introduction*: it is linked with an HTML page to explain the test section. *true-false*: it is linked with an HTML page to show ten true-false questions to let students choose true or false. *Multiple choice*: it is linked with an HTML page to show ten multiple-choice questions to let students choose one right answer.

BEST COPY AVAILABLE

Menu: by clicking this button the current self-test interface switches to self-test list interface so that students can choose different self-tests from the links. *Back*: by clicking this button the current self-test interface switches lesson interface. The self-tests interface is shown on Figure 3.



Instruction

Please choose any type of test for practice.

After finish it, please compare yours with standard answer by clicking *Compare Answer* button.

Figure 3: Self Test Interface

The Photo Gallery section, links an HTML page with nine insect images to provide some direct impression of insects to students. There is a separate Animation Directory. It includes two graphics animation applications written in OpenGL. One is a butterfly and the other is a dragonfly, the students can control these by using the keyboard.

Conclusions

The CD-ROM Entomology course has animated pedagogical agents to represent the course instructor role. Course contents are organized into four sections: Lectures, Exercises, Tests and a Photo Gallery. With text-to-speech technology, Haptek VirtualFriend 4.1 plugin and software development, students can be instructed as verbal and visional ways simultaneously. There are several significant features in this course, such as inspiring course contents, attractive teaching style, flexible study arrangement, and cost-savings for both students and educators. All those features satisfy the high education trend in the new centaury. This CD-ROM Entomology course proves to be a good teaching tool as evaluated by one of the students of this course. According to this success, this new education style may be considered to apply on various courses in CALCE Electronic Products and Systems Center, University of Maryland in the near future.

Open Goal-Based Scenarios: An Architecture for Hybrid Learning Environments

Lin Qiu and Christopher K. Riesbeck
Department of Computer Science
Northwestern University
Evanston, Illinois 60201 USA
{qiu, riesbeck}@cs.northwestern.edu

Abstract We describe a software toolkit called Indie, for building hybrid Investigate and Decide (Indie) learning environments. In Indie learning environments, students can run simulated experiments, construct reports arguing for different claims, and submit these reports for critiquing. The Indie learning environment is one example of the Goal-based Scenario (GBS) learn-by-doing environments. Previous examples of GBS systems have been self-contained software-based learning environments. The content of the learning environments is always pre-defined, which leaves little space for open-ended activities. We overcome this problem by creating an architecture for hybrid GBS's that provide the option for having human coaching in the learning environments. This brings the possibility of having open-ended activities in GBS's as well as the opportunity for incrementally augmenting the content at instruction time. Indie has been used to construct Corrosion Investigator, a learning environment for engineering undergraduates in the domain of biofilms.

Introduction

The Goal-based Scenario (GBS) (Schank, 1994; Schank, Fano, Bell, Jona, 1993) framework for computer-based learn-by-doing (Dewey, 1916) environments is designed to engage learners in active purposeful learning (Bransford, Brown, Cocking, 1999). A GBS begins by giving learners some large realistic problem that needs to be solved. With support from the learning environment, students learn target skills and underlying concepts in pursuit of goals within a context rich environment. The content of a GBS system is authored in advance based on real-life cases, common pitfalls, war stories, and so on. GBS's provide not only a simulated world for interaction, but also modules for expert coaching and critiquing, so that the learners are not limited by the availability of domain experts.

In order to support such computer-based coaching and critiquing modules, GBS's have to be closed world systems. The vocabulary of operations and situations has to be specified in advance so that rules can be written to provide accurate and timely feedback. Once deployed, learners can only do what the GBS has been prepared to support, so designers have to anticipate every action a student might want to do, and the most appropriate feedback for such actions in all situations. GBS's require significant upfront design, implementation, and piloting by content developers working with domain experts and test subjects, in order to provide learners with a rich challenging environment. There is no easy way to add new operations, coaching, or critiquing later in order to incorporate new developments in the domain or locally relevant content. Furthermore, it is difficult for GBS systems to accommodate the interests of open-ended teaching and learning paradigms (Collins, Brown, Newman, 1989; Gardner, 1991; Papert, 1993).

To overcome the above difficulties, we have been creating an architecture for hybrid GBS's and applying it to a subclass called Indie (Dobson, 1998). In Indie learning environments, students learn how to solve problems by running experiments and using the results to support or refute possible diagnoses. A hybrid Indie learning environment does not only have traditional support in a GBS from the computer, but also allows human experts in the feedback loop to handle totally open-ended inputs from the students that previously are not allowed and understood by the system. Open-ended activities are therefore made possible with the help from the human expert. Meanwhile, new material can be introduced in the interactions by students and faculty during the running of the GBS. There no longer exists a point where the system content is frozen. Introducing a human expert into the learning environment makes both the learning environment and the development of the learning environment open.

Indie Architecture

Indie is a content-independent Java-based software toolkit that includes a content authoring tool and a runtime learning environment (Fig. 1). The content authoring tool provides a user-friendly knowledge input interface for experts to enter content knowledge into a knowledge base, e.g. scenario challenge, experiment options, result generation methods, and domain background information. The Indie Learning environment reads in content files and become instantiated to a web-based learning environment. The Indie learning environment has a common interface, including support for a splash screen, a welcoming "challenge" document, a "background" screen where students can browse materials describing the scenario and domain content, a "lab" interface where students can order tests and collect results, and a "report" interface where students can construct arguments for and against possible diagnoses, using the evidence gathered from the tests. Indie learning environments automatically generate lab test results based on requests from students and provide scaffolding for students to construct arguments. Working as middleware between the students and instructor, it tracks student working progress for the instructor and lets the instructor role-play characters in the scenario.

- Provide feedback on student work
- Track student working progress

Figure 1: Architecture of the Indie toolkit

Though authoring time and instruction time in Figure 1 respectively refers to the time when the expert inputs knowledge into the system and the time when the instructor works with the students through the learning environment, they are not necessary separate periods. In other words, the instructor can work as the expert to augment the system while engaging in working with the students. Having the instructor working in the learning environment keeps the system from totally depending on pre-defined content, which is crucial when the content knowledge in the system is still under development.

An Example: Corrosion Investigator

We used Indie to build the Corrosion Investigator application, a learning environment for engineering undergraduates in the domain of biofilms. In the learning environment, students take the role of consultants to help a company determine the cause of pipe corrosion. Students need to make conscious decisions about which tests to run and which test results support the claims they make in order to solve the problem in a timely and economical manner. This requires students fully understand the purposes of the tests and the implication of the test results.

To run tests, students go to the Experiment page (Fig. 2). Here, students can look for tests by entering test names into a textbox. Tests matching the name will be shown. Students can view the description of the tests and possible variable values for the tests. Currently, there are five tests in Corrosion Investigator. A few more will be added. If no test matches the name that students enter, students will be asked to try another name, or email the Scientific Consultant, a character played by the instructor in the scenario, for help. Using an open-ended interface for test names forces students to research and brainstorm about what tests might be relevant. It also allows tests to be used that the scenario authors hadn't predicted. Hence, the problem solving activity is more open-ended and closer to real life situations. Such activities help students develop adaptive expertise (Bransford et al., 1999). New tests and results can then be incorporated into the system for reuse by future students. This approach does require an expert in the loop, though, to interpret reasonable but unexpected test names, and to generate plausible test results on the fly.

BEST COPY AVAILABLE

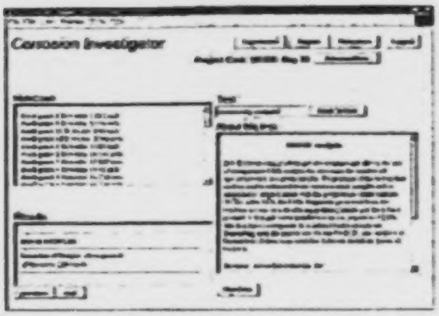

Figure 2: The Experiment screen in Corrosion Investigator.

When the test results become available, they appear in both the Notebook and Test Results area (Fig. 2). Test Results area displays the test results in a readable manner. The Notebook records all the test results that the user has received in a list that can be used for constructing a report. Most of the numbers in the test results are generated randomly based on constraints specified in the domain files.

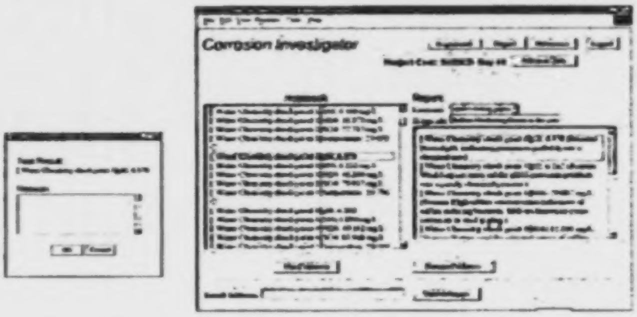

Figure 3: The Report screen in Corrosion Investigator.

When students feel they have gathered enough information, they can go to the Report screen (Fig. 3), make claims, and apply evidence in the Notebook towards that claim. Students need to specify the reason for using a test result as evidence. They also need to use many pieces of evidences to support their claim, because the strength of the argument, and its freedom from irrelevant evidence, is a key area for critiquing. After finishing constructing the argument, students click the Submit button to submit their reports. The system emails the report and the data in the Notebook to the instructor. The instructor reviews the report and emails feedback to the students. Students then continue working based on the feedback.

Related Work

A previous version of Indie was developed in Lisp on the Macintosh by the Institute of Learning Sciences (ILS) at Northwestern University. Over a dozen of Investigate and Decide learning environments were built with the old Indie (see Dobson, 1998). Our new version is Java-based for portability and web-delivery, and uses XML files to represent the domain content. Most imporantly, the new Indie supports human coaching and critiquing as well as much more complex tests, and random test result generation.

See Dobson (1998) for more related work.

Future Work

Six first-year graduate students in the Civil Engineering Department in Northwestern University used Corrosion

BEST COPY AVAILABLE

Investigator in a class in May 2002. After using Corrosion Investigator for 3 weeks, students completed a survey regarding their experience. Their average score to the statement that "overall, this is an excellent system for doing the project" was 2.16 on a scale of 1 to 5 (1 stands for Strongly Agree, 5 stands for Strongly Disagree). The question "How difficult is it for you to find out the right test to run?" got the most negative score, 3.83 on a scale of 1 to 5 (1 stands for Very Easy, 5 stands for Extremely Hard). This shows that the most difficult aspect of the interface to use was the mechanism for finding tests to run. Improving the interface for finding tests to run thus becomes one of our future research issues. Other parts of the system were considered not difficult. As for the professor of the class, the software significantly reduced his work during the project phase, especially on test result generation.

The content knowledge for Corrosion Investigator was written in XML format directly without using the Indie authoring tool because the tool is still under development. We are using a class-based dialog box approach that proved quite successful in the previous Indie for building the tool.

Acknowledgements

This work was supported primarily by the Engineering Research Centers Program of the National Science Foundation under Award Number EEC-9876363. Matthew Parsek, an assistant professor in Civil Engineering, developed the original biofilm course that Corrosion Investigator was based on. He later expanded and refined the content in his course for Corrosion Investigator. Ann McKenna, a post-doctoral fellow in the School of Education and Social Policy, guided the development and evaluation of the original course.

Making Your Online Learning Environment a Success
Clemson University's Approach

Carla Rathbone
Director of Collaborative Learning Environment
Clemson University
United States
bone@clemson.edu

Abstract: A popular topic of discussion in higher education is online learning environments. Everyone wants to collaborate, learn anytime and anywhere and do this with little or no experience required. Competition between commercial versions of online class environments, locally developed versions and a hybrid of the two has inundated our educational institutions. Regardless of the choice, how do you make it succeed? More importantly, what makes faculty and students buy in to this new way of teaching and learning? This article looks at how Clemson University is addressing these issues of what makes an online learning environment useful and how to encourage the innovative use of this environment. We will conclude with a look at how we have been able to expand our services to a portal concept that addresses the computing needs of all users at Clemson and extends these personalized tools and services for use in the classroom and the workplace.

Introduction

Clemson University is a public, land-grant research university with a total enrollment of 17,465 students and approximately 1200 faculty. Clemson's Collaborative Learning Environment, better known as MyCLE, was created in 1997 to lead the university in incorporating technology into the teaching and learning process, providing a wide range of technological services for use in the classroom. This online learning environment was developed internally to provide collaborative work space and web tools for all 6000 class sections each semester with no administration required by the professor. This system integrates information from our legacy Student Information system, Novell Directory Services and numerous customized applications. Access to the online learning environment is through a single computer user ID and password. Membership in the class workspace is automatically maintained through a dynamic link to the Student Information System. Each class has a consistent suite of course tools and file folders with common folders for turning in and reviewing homework, storage of class materials (such as course syllabus and assignments), public web folders, team folders, student surveys, grading, discussion boards and library reserves. In support of both synchronous and asynchronous learning, Clemson University's online learning environment is globally accessible fromboth our network and the web.

Background

The Collaborative Learning Environment department is department of the Division of Computing and Information Technology (DCIT) and was established with support from the Provost office with a $150,000 annual funding. We have continued to receive this funding every year to support training positions, provide faculty incentives and purchase new hardware and software for training and faculty development labs. Additionally, DCIT restructured its academic support to focus on supporting this new learning environment. Currently the CLE department consists of 12 full-time employees, six to eight students and two faculty fellows to promote and support the use of MyCLE.

Clemson University's Approach – Support and Services

Communication and support have been the cornerstone of the implementation process of our online learning environment for both faculty and students. The approach used by the CLE has itself been a collaborative effort and included many departments and groups across campus. Partnerships have been formed, new training programs established and student and faculty labs upgraded as outlined below, all as part of creating and supporting a successful collaborative learning environment at Clemson University.

Partnerships

- Office of Teaching Effectiveness and Innovation (OTEI) and CLE share office space and work together to assess the technological needs of faculty in teaching and learning. Joint workshops and seminars are provided on a regular basis.
- Student Government and CLE worked together to produce a syllabus repository for students. This repository of course syllabi allows students to research class descriptions prior to registration. It also allows faculty to automatically upload their class syllabi to MyCLE.
- The University Library and CLE developed a process to allow the library to post class reserves electronically through the university's online learning environment.
- CLE works with the Office of Off-campus, Distance and Continuing education to determine standards and tools for distance learning and co-sponsor seminars for faculty to learn how to use these tools.
- CLE Advisory Board (consisting of 2 faculty representatives from every college and student representation) evaluates the needs of faculty and students in the use of the online learning environment.
- CLE faculty fellows (faculty members who are given additional funding to serve) act as mentors to their colleagues in the use of technology. The faculty members sponsor workshops, address discipline-specific needs, write articles for the faculty newsletter and assist in beta testing new tools and features of the online learning environment.

Training and Support Programs

- A computer literacy program was designed and implemented for 100 level courses, specifically English 101 to introduce students to Clemson's computing environment.
- In-class training for course-specific instruction may be requested by faculty and is held during the regularly scheduled class period.
- Short courses are offered each semester to all faculty and students
- One-on-one consulting is available to assist faculty and students in the use of MyCLE.
- A newsletter, Faculty Directions, is published quarterly that showcases the work of faculty using technology in the classroom.
- Faculty training classes are scheduled each semester covering the use of MyCLE and supported web and multimedia application.
- Faculty Laptop development program is implemented this Fall to address faculty use of laptops (required this year in College of Business and Behavioral Science, College of Engineering and Science undergraduates and also for the first year MBA students).

Labs

- A faculty development/multimedia lab was created for scanning of text files, images/slides, video capturing and editing; color printing, digital media and web page creation.

- A "virtual laptop" environment was developed allowing students to have access to files, programs, email, bookmarks, etc. from any lab computer on campus or dorm room
- Over eighty classrooms have been converted to "smart classrooms" and equipped with a podium containing a network-connected computer, VCR, cable TV connection, and with a ceiling mounted high quality projector.
- Laptop requirements have been implemented this semester to include freshman in College of Business and Behavioral Science, College of Engineering and Science and also for the first year MBA students.

Conclusion

This level of services and support throughout the CLE, combined with the ease of use and availability of our online learning environment, has proven to be successful with faculty and students. Currently 85% of all students and teaching faculty representative of all five colleges use some components of the online learning environment in their classes. As more faculty and students become comfortable using the tools and features, the gradual transition to online learning becomes a reality allowing more flexibility and alternative methodologies in the teaching and learning process.

The CLE continues to develop and expand the services offered in order to meet the needs of the Clemson University campus users. Over the past year we have been able to implement the portal concept to extend and personalize these services to administrative units across campus because of the successful use in the classroom. Work groups are automatically created in addition to scheduled classes to provide access to these tools and services in the classroom and workplace. This includes various web tools, shared file space, personalized applications and access to university systems. Some of the current uses for work areas include our SACS Self Study groups, student organizations, administrative business units and student advisory committees.

For more information go to http://cle.clemson.edu. For a look at the online learning environment, contact clc-l@clemson for a guest account and enter at http://mycle.clemson.edu.

Figure: 1: Clemson University's Online Learning Environment (MyCLE)

Without any doubt, there are special challenges to providing adult education as such in a developing country.

The first and foremost challenge is to spread a relatively scarce resource - knowledgeable content providers (i.e., lecturers) - over a huge geographic area. Another challenge is to find the necessary financial resources to fund the delivery of adult education in the face of pressing basic necessities such as providing primary health, welfare, and safety care. On top of this, in South Africa there is the added imperative of an urgency to empower millions and millions of illiterate adult black South Africans due to the educational backlog because of the previous government policy of apartheid.

Against this background, a new company with the apt name of *eDegree* was formed in South Africa with a capital investment by PricewaterhouseCoopers three and a half years ago, with the specific objective of harnessing the advantages of e-learning as one of the most viable solutions to meeting the above-mentioned challenges.

In many ways, in retrospect, it was a case of "fools rush in where angels fear to tread". I believe we were one of the very first companies/institutions in the world to deliver a fully-fledged Bachelor of Commerce, as well as an MBA degree, completely online. At the other end of the spectrum, our Adult Basic Education and Training programme (i.e., a fast track for illiterate adults from grade 1 to grade 9) delivered on CD was surely a world first.

I would like to share my company's experience in providing e-learning to the African continent (and, more specifically, in South Africa) with you. During this time, we have learnt to move at lightning speed, to redirect and re-engineer every two to three months, to navigate through uncharted waters, building new models as we progressed and, yes, also from time to time looking back in amazement at our ignorance 30 days before.

By utilising e-learning, the expertise of the relatively small pool ofhigh-level content providers who are able to contextualise knowledge within local circumstances is being distributed on a national level.

Furthermore, course delivery via a virtual classroom (text and/or audio), synchronous and/or asynchronous, lends itself admirably to bringing learners into contact with peers and lecturers all over the country and continent, drawing on one another's unique yet comparable third-world circumstances. (Bandwidth restraints in Africa limit the use of streaming video to a very large extent at this stage.)

On top of this, e-learning now provides African learners with direct access to the best international resources available through the WWW or by means of e-mail for the first time.

It is important that one should recognise that there are different categories of adults who would benefit from online learning. Young undergraduates have learning requirements that are quite different from those of highly motivated mature learners in the professional workplace. And how on earth does one go about teaching a completely illiterate adult to use a computer? Does it make any sense at all to use such a highly sophisticated piece of technology to educate somebody who has never even used a pen or pencil?

An understanding of the relevance of learning requirements and styles must precede the design and implementation of learning programmes. The learning environment and the facilities available to support the learner, both online and off-line, should reflect the elements of sound pedagogy relevant to the groups concerned.

Developing a training course for the South African market requires developers and providers to create courses that are not simply didactic, but that also reflect the principles of learner-centredness, lifelong learning, flexibility in learning provision, the removal of barriers of access to learning, recognition of prior learning, provision of learner support, relevance, differentiation, redress, nation-building and non-discrimination, critical and creative thinking, flexibility, and progression.

It is neither desirable nor appropriate for large numbers of academic staff (even should they be available) to become experts in the use of authoring software. In any case, the design of effective courseware materials involves much more than the use of an authoring tool. In our opinion, it is more appropriate in the development of materials that subject matter experts should be creative and work with and advise experts in instructional design, in graphical design, in the production of audio and video materials, and in a range of other services to ensure courseware of high quality than for them to try to do everything themselves.

Therefore, the core business of *eDegree* is to assist public and private higher education institutions and companies to redesign and package their course content to optimise the e-learning capabilities to the full. This we do by training faculty in e-learning instructional design principles and, thereafter, digitalising their courseware on a five-tiered scalable index according to different parameters such as cost, target population, and technical considerations.

At *eDegree*, we also take responsibility for the administration and management of the delivery of the e-learning courseware if the client so prefers, with the academic institution at all times the custodian of all matters pertaining to academic standards.

e-Learning courseware design

Partly to help economise on development costs, increasing interest is being shown in the concept of reusable "learning objects" defined as the grain size of the smallest unit of production within learning material. We use the term "learning object" to refer to the smallest study unit that a learner might wish to take: full courses should be structured by combining such small units. Structuring course content in the form of independent learning objects implies that multiple learning outcomes and, therefore, multiple curricula needs can be met by re-using the same learning objects. This has the advantage that different qualifying authorities (universities, colleges, and companies) can select relevant outcomes or objectives for learners from the same pool or repository of carefully constructed learning objects. The learning objects are relatively self-contained from a learner's perspective and are structured to enable the learners them to be assessed.

To provide this level of flexibility, the ideal is that *eDegree* will need to make available stand-alone learning objects for learners throughout the African continent, which could form part of a fuller course leading to an award, or they could simply be independent units prepared for a specific market. This will enable potential consumers to select learning objects, either separately or in combination, to suit their needs – albeit with guidance about their coherence and about the possibilities for an award.

Developing material in the way we propose requires subject expertise to be combined with a range of skills associated with instructional design. The development process is time-consuming and expensive, which is one reason why these scarce resources are centralised in one specialised service provider such as *eDegree*.

Constructing courseware by means of learning objects implies that no duplication – and, therefore, unnecessary use of an expensive limited resources – takes place. On the contrary, extensive reuse of knowledge is made, packaged in such a way that immediate updates at relatively low cost can be done quickly.

This way of organising knowledge does, of course, have enormous implications for courseware design. But even more importantly, it demands a whole new way of thinking about curriculum development and structuring of qualifications.

One of the outcomes of this approach is that the World Bank has awarded us a grant for developing a world-first Online Authoring course, i.e., an individualised online programme to train subject matter experts in the unique instructional design methodology necessary for designing an online learning experience, enabling them to transform their existing content knowledge to optimise the benefits of the online learning environment. This has been a formidable challenge and a tremendous opportunity.

We have succeeded in developing a curriculum design through a flexible modular architecture built on the learner's personal (lecturing) profile, his/her target audience, different learning styles, etc. In practical terms, this means that instead of a linear approach, SMEs are prompted to follow a non-linear route through the learning material in a way that best serves their needs and those of their target audience. By first assessing which learning outcome a learner lacks, he or she is then branched to the specific learning object underlying success in mastering the outcome.

Within the course content, different instructional design principles and how they impact on learners from varying cultural and educational backgrounds are addressed. Not only does this add to the applicability of the programme within the different educational contexts worldwide, but it is also believed that from our experience gathered in the multicultural South African educational environment, we are uniquely positioned to develop a novel product of this nature.

In order to add functionality to the front-end tools, the use of artificial intelligence to automatically evaluate the didactic applicability of selected multimedia features has been developed – also a unique attribute of this programme.

An unique e-learning challenge

It is imperative that, given the African education scenario, special attention is given to training of adults on lower levels also. It is with this in mind that *eDegree* has put a very special effort and millions of rnads into developing an Adult Basic Education and Training (ABET) programme, essentially training illiterate adults to read and write.

The term "ABET" connects literacy with basic, general adult education and with training to enable income generation. ABET learners exist in a wide range of learning constituencies, including organised labour in the formal economy, self-employed and underemployed people, the unemployed youth and adults in urban areas and settlements, the rural unemployed, and women heads of households in both urban and rural areas.

The ABET audience is diverse. It is also located in the dynamic world of globalisation and technological advance. It is vital then that material provided to meet ABET learning needs is flexible, so that it works within a wide range of contexts. Our programme lends itself to two modes of delivery: the traditional classroom-based method and the computer-aided method guided by the facilitator. The computer-aided approach to ABET aims to bring together classroom-based and distance learning, taking the best from both approaches and forming a new method focused on meeting individual learner needs.

While ABET learners can never be expected to complete courses independently, the lessons learnt in forming sound distance learning principles relate to the independent nature of self-paced learning. Incorporating multimedia into the learning equation enables learners to learn at their own pace, while still enjoying the support and guidance of a facilitator and the camaraderie of fellow learners.

The benefits of e-learning in an ABET context are many and varied: over and above the benefits of monitoring capabilities, and providing independent, self-paced learning, instruction given is standardised, and e-learning allows for easy adaptation of material. The endless capabilities of multimedia with sound, animation, and graphics make explaining concepts to learners at lower levels far easier. A learner who is able to watch the animation of different shapes moving together to form letters, letters moving together to form sounds, and sounds moving together to form words is able to "experience" a new concept, rather than accept static representations of the concept, filling in the blanks where necessary. Reference tools come alive in front of learners' eyes – an alphabet library, combining the name of each letter, the sound it makes, how to write it, and an associated picture, makes learning to read and write more than memorising lists of sounds and shapes; it becomes an integrated learning *experience*.

The process of developing an effective e-learning programme becomes significantly more complex when South African developers are faced with the challenge of providing programmes in 11 official languages.

The challenge is compounded when the programme being provided is essentially one enmeshed in language, such as an ABET course. Teaching someone to read and write in English is vastly different from teaching someone to read and write in another language. Think of a literacy course in French. The French language is bound by grammar rules such as the masculine and feminine gender of nouns. Simply translating a French literacy course into English will not produce a meaningful programme. It is not only grammar rules that cannot simply be translated – think of idioms, poetry, and humour specific to the English language. Before the process of developing content for courses in 11 languages can begin, generic components must be isolated, language-specific components for each language identified, and a way forward mapped out. Translators and language experts become vital new members of the team.

But the challenge does not end here. Instructional designers, graphic designers, and programmers require an understanding of the content in order to mould it into a meaningful learning experience. The answer cannot be to simply form a team for each language, where each member speaks the language concerned. How would one control quality and consistency? The likelihood of finding a person who speaks all 11 official languages AND with enough knowledge and experience to manage 11 multimedia production teams is slim. Furthermore, quality control and monitoring of programmes in 11 languages once these programmes have been implemented is no easy task.

Conclusion

With Africa and, more particularly, South Africa having been relatively isolated from the rest of the world for very long for various reasons, we take special care to keep at least up to date in terms of fast-moving international best-of-breed e-learning practices.

Globalisation demands high productivity, an advanced skills base, and a competitive edge. We should maximise our potential in focus areas, while taking advantage of international skills in other areas. Globalisation offers us the opportunity to compete in world markets for the first time. This enables us to make use of state-of-the-art technology, while sharing knowledge and ideas with specialists who have a common passion and purpose.

Life on the Bleeding Edge: How Emerging Technologies Can Help New Teachers

Pamela Redmond
Teacher Education Department
University of San Francisco
Redmond@usfca.edu

David Georgi,
Teacher Education Department
California State University, Bakersfield,
dgeorgi@csub.edu

Abstract: The Teaching Learning Interchange (TLI), a federal Preparing Tomorrow's Teachers to Use Technologies project, will be in its second year of applying several emerging technologies to help new teachers in several ways. This presentation will report actual second year results compared with the first year expectations listed below.

The Teaching Learning Interchange (TLI), a federal Preparing Tomorrow's Teachers to Use Technologies project, will be in its second year of applying several emerging technologies to help new teachers in several ways. This presentation will report actual second year results compared with the first year expectations listed below.

The target population consists of "preintern teachers," a designation in California for teachers who are not credentialed and have not passed subject matter competency. The intent of the preintern program is to provide a way for those wishing to enter the teaching profession to attain subject matter competency and a credential while they are working in the classroom. The program originated because of a severe teacher shortage in California.

TLI has partnered with 15 county offices to have access to preinterns and corporate partners who are developing new technologies.

ClearPhone provides software for conducting video conferences among small groups anytime/anywhere via Internet access. TLI identified a number of subject matter science specialists (the area of greatest need) from the Exploratorium. They are being connected with preinterns who need to attain subject matter competence. Each participant will be given a net cam, whiteboard and software. Online meetings will be conducted in which several preinterns can meet with a specialist and discuss topics covered on the Praxis science test. The whiteboard allows participants to share lesson plans and student work samples.

Expectations are that both the specialists and preinterns will give ClearPhone high marks in the ability to meet from distant locations. Those in rural areas with long distances are expected to have similar benefits to those in congested urban areas, notably the efficiency of meeting without the disadvantages of travel to a common location. The preinterns in the project are expected to score higher on Praxix than preinterns in general.

Lesson Lab provides online video of classroom practice that is particularly useful in helping preinterns understand and plan for the complexities of classroom management and lesson delivery. LessonLab has a unique software package that allows instructors and preinterns to time index a video of classroom practice while online. For example, an instructor can create an assignment to demonstrate a particular teaching practice, like responding to the efforts of learners. The assignment can provide a link to where an example, say at 12 minutes 32 seconds of a 60 minute video. The assignment can then require preinterns to view all or some of the entire video and mark where they see examples of effective or ineffective practice and write narrative descriptions of their perceptions. When the assignment is completed by all the preinterns, a chart showing all the examples marked by preinterns can be displayed, forming the basis of a dialog on examples marked by many and those marked by only one or two. The advantage of this approach is that teaching is shown within a realistic context including both effective and ineffective teaching practice. Preinterns can explore practice via synchronous and asynchronous online discussions to obtain deep levels of understanding of the complexities of teaching. Both instructors and preinterns are expected to report that this technology is helpful in improving their classroom management, lesson planning and delivery.

Apple Computer recently redesigned its Apple Learning Interchange (ALI) to include video cases along with Units of Practice for particular lessons and links to related resources. A search engine is included on this portal that links Units of Practice to state and/or subject standards. Preinterns will be given structured access to the ALI. They are expected to report that the ALI is useful in obtaining and adapting lesson plans, viewing examples of successful practice and accessing resources and standards.

In conclusion, the experiments of the TLI in providing such state-of-the-art technology to new teachers is expected to produce a wealth of useful applications that have great potential in future teacher preparation programs, as well as identifying a number of potential problems that go along with such innovations.

Diversify, Diversify, Diversify! Why Gender Mainstreaming in Educational Media Does Not Mean one Size Fits All.

Bernd Remmele

Bernhard Nett

Frank Roehr

Britta Schinzel

Benjamin Stingl

Tanja Walloschke

Institute for Computer Science and Social Studies
Dept. 1: Modelling and Social Impacts – RION Rechtsinformatik Online
University of Freiburg, Germany
remmele@modell.iig.uni-freiburg.de

Abstract: Distant Education and Internet-supported classroom education pose specific problems to the establishment of gender equality in Higher Education. Instead of discussing these problems from the perspective of insufficient competencies among women, it is stressed that the specific media have to allow different (also female) user strategies. Especially the integration of presentational and communicative functions into educational software promises to show general (ungendered) success. These assumptions will be rested on experiences of the Internet based teaching network RION.

Introduction

'RION – Rechtsinformatik Online' is an Internet based teaching network of nine German universities and three different disciplines, i.e. law, informatics, and economics (Rechtsinformatik is the German expression for computer and law - C&L). It is designed to create an Internet platform including a learning space for the field of computer and law.[1] This field is gaining more and more importance with the new media and it is constantly changing with them, however it does not fit into the traditional structure of German law teaching. So there are some gaps, which RION tries to fill with its interdisciplinary, and ICT based approach.

The authors, who are an interdisciplinary group (computer science, law and sociology) themselves, are responsible for the didactical consulting, the gender mainstreaming and the evaluation of the whole project. One main objective of our evaluation is therefore the problem of gender and new media. Though we raise data about computer literacy according to the present computer practice and get the expectable result (i.e., the male practise is 'more advanced' than female), we do not think that this is mainly question of deficient female competencies. The statement that there are such differences between the sexes in the usage of ICT in Higher Education does not mean women have to become like men; rather we have to reconsider the interaction structure of the media and the practises they allow in order to promote the implementation of software that can be used successfully by different users. Why should different user groups (there are more differences then that between men and women) adapt to the media instead of adapting the media to the different interest and the relating competencies.

From this perspective computer literacy has to be seen in the framework of a definition of media competence, which is conceptualised in a more complex way than just by superficial present practise. A timely definition of media competence has to add contextual knowledge about the media to the limited determinations of mere ICT handling; this involves some critical faculty especially regarding the social dimension of the media and their usage (Cf. Baacke 1999). We want to point out that this comprehensive conception also involves another perspective on the C (commu-

BEST COPY AVAILABLE

nication) and its connection with the I (information), because the ways communication is organized in educational software – if at all – do not reflect the whole spectrum of services and features, demanded by different user interests. Of course this does not sounds really new, as most of it complies with constructivist pedagogics. Constructivism also focuses on contextuality. Information has to be framed in a given context to be meaningful, and this means also that it is socially situated. So when contextualization was discovered as a chance for education in the nineties, constructivism became popular in pedagogics. Therefore regarding ICT in (higher) education the interactive potential of the computer should be moved into the center of interest. Students should no longer be considered as mere consumers. Instead, their involvement ought to be promoted by making it decisive in regard of what happens (Cf. Siebert 1999; Specht 1998).
As gender mainstreaming is an enterprise that goes to the roots of organizational and technological structuring, it is clear that gender mainstreaming is directly concerned with possible user strategies in the realm of educational software. One of our basic assumptions is that the disciplinary (learning) culture of informatics is decisive for the learning models implemented in educational software (regardless of the design of the user interface and similar apparent qualities, which are mostly expressions of an analogous production process). This model is determined by the singling out of the learners (i.e. no grouping in the strict sense of the word takes place), assumed standardized basic knowledge, and clear-cut separation from other scientific disciplines and practical usage. In the respective software we thus have mainly space for lecture-scripts, and - if at all - communication-tools, which are somehow stuck on to the central presentational core, without building a functional unit.[2] This obviously is not constructivist.

Evaluation Results

A basic survey carried out at the beginning of RION showed in regard to the (Western) Internet-standard-applications more or less equal results for men and women. However there were significant differences in advanced computer use or - to say it in another way – in male domains, like hardware, programming, games and discussion boards to the disadvantage of female participants. These results are supported by the fact, that in discussions of male students the computer is an issue more often than among female ones: so technical expertise is exchanged more frequently within male dominated networks.
Certain internet tools tend to support gender-specific communication styles, and especially discussion boards do so in a way, that has often lead to frustration of female participants (Cf. Herring 2000). With the data of our survey we can establish the thesis that gender-specific user profiles, in consequence of specific media biographies, correlate with diversified self-conceptions: In regard to the self-estimation of their computer competence, female students rate themselves significantly lower.

"I know, that I can handle my computer well."				
	exactly	rather correct	rather not correct	no
female (20)	10.0%	50.0%	40.0%	0.0%
male (49)	40.8%	49.0%	10.2%	0.0%

We asked students of law and economics from different universities, who are studying C&L,[3] with a questionnaire to rate the assertion "I know, that I can handle my computer well." As the table shows no one answered 'no' and half of the women as well as half of the men choose 'rather correct'. However 40% of the female said 'rather not correct' whereas the same percentage of the male answered 'exactly'. This clear difference regarding the 'computer self efficacy'[4] and the respective gendered satisfaction pattern leads of course to lesser practice in this field, so that we get a vicious circle of less experience and lacking contentment.

Experiences with the MOO used by RION (called JurMOO) may point at a way out of these circumstances.[5] To understand this claim we first have to know what makes a MOO so special. A MOO is a Mud (multi-user-domain) object oriented. This means that the whole setting including the "characters" is programmed in an object-oriented manner - and the users themselves may change all these elements. If you look at the user interface of a MOO[6] -

---

[2] Kirkup & Prümmer (1997) also connect gender problems with the design of communication features. "For distance education to take this seriously, systems must have designed into them connection networks among students with the chance to communicate and meet."

[3] Though in general the proportion of sexes in law and economics is balanced, where there is the choice more men are taking courses in C&L.

[4] Cf. http://www.chssc.salford.ac.uk/healthSci/selfeff/selfeff.htm

[5] http://lem.iig.uni-freiburg.de:7000/

[6] Basically a MOO can be used via Telnet; the JurMOO of RION can also be accessed via a browsable Java emulation (http://lingua.utdallas.edu/encore/).

which admittedly needs some familiarization - there are three 'frames'; on the right side there is something like a web page, the 'rooms' of the MOO; and on the left side there are the two frames – a big one on top, a small one at the bottom -, which are something like a mixture of a chat client and a command line. With the different commands you can change the structure and the content of the 'rooms' and objects. Everybody is represented by an individual character. MUDs and MOOs are normally used for text adventures, with battle lines and quests created by the players themselves in the framework of some fantasy plot; but they also find some usage in Higher Education contexts.[7] So MOOs are bad means for simply distributing traditional top-down teaching (Bruckman & Resnick 1995), but instead are able to support active groups of learners.

Depending on the structure of the MOO there is a diversity of possible things to do: usually 'move' from one 'room'/web page to another, give a message to all in the same room ('say'), give a message to one specific character, write mails, and describe, change or build rooms or objects; but there also special things to do like marry (one or more persons), smoke a cigarette, cuddle etc. … 'Move' and 'say' are of course the mostly practised actions. And because these actions are tightly interweaved on the user interface, it can be said that the distinctive feature of a MOO is that it directly combines communicative and presentational functions. This complex condition allows diversified user strategies. Thus the potential of the MOO is its combination of information and communication, and the easy shifts between them (Hoadley 1999).

Among other purposes RION used its JurMOO for the preparation of a two-day-workshop on broadcast law for law students.[8] For several weeks before the workshop the participants discussed the subjects of their presentations with each other and with tutors, and they built a 'room' where they put their table of contents etc. for annotation.[9] The development of the whole course was evaluated by questionnaires (e.g. regarding computer literacy and self efficacy), interviews and analyses of the server log of the MOO.

	'move' - first 150	'move' - total	'say' - first 150	'say' - total	actions all together
female (16)	53 %	56 %	37 %	36 %	100 % (8762 actions)
male (18)	73 %	67 %	21 %	26 %	100 % (8827 actions)

The most striking result of our evaluation is the existence of different however converging user strategies for females and males.[10] The table shows the percentage of 'move' and 'say' in relation to all used commands specified by the sexes, in respect to the first 150 actions of each person and to their total amount. Obviously women 'say' more and 'move' less than men at the beginning; women still 'say' more on the long run (Also female messages in average are longer, so that a female did 'say' almost twice as much as a male during the whole course.[11]) While organizing the common task the gendered preferences converge however to a certain degree. There is a development especially with the male participants. Whereas women only 'move' a little bit more with time, men clearly 'move' less and 'say' more.[12] This convergence of user strategies throughout the virtual seminar was however only made possible by the special characteristic of MOO, the integration of communicative and presentational functions. And it were the men who 'adapted' primarily.

Thus concerning the satisfaction pattern, there is another interesting result. Female students were more content with the use of this tool than the male ones. Comparing the ratings of male and female students, both evaluated JurMOO´s influence on the quality of the individual presentations for a final face-to-face situation and the overall help provided by the tool pretty equally. In contrast, a relatively strong positive deviation of the ratings of the female students existed for JurMOO´s contribution to the understanding of co-students and their presentations (in the mean 5.4 for women to 4.3 for men out of a 0-10-scale), while positive deviations of the male ratings are related to the

[7] E.g. http://clark.colgate.edu/dhoffmann/text/ACTFL2000/moovass1.htm, telnet://moolano.berkeley.edu:8888/; cf. Holmevik, & Haynes 2000.

[8] http://www.uni-muenster.de/jura.tkr/alte_version/lehre/materials/Verlaufsplan Seminar WS0102.pdf

[9] Due to the constraints of German mass faculties like law, to discuss a presentation in advance is more than unusual. Normally nobody has an idea of the connections of his subject with that of a fellow student, therefore he has also quite little interest in the presentations of others.

[10] Regarding gender-different but converging learning styles cf. Campbell 2000, p. 137.

[11] The average length of messages was for females: 35,39, and for males: 31,78.
In average a female did 'say' 7081 signs, whereas a male did 'say' 4191 signs.

[12] This table shows the development in smaller steps.

	0-49	50-99	100-149	150-199	over 200
female 'move'	50 %	54 %	54 %	56 %	57 %
male 'move'	69 %	79 %	71 %	50 %	66 %
female 'say'	39 %	37 %	35 %	35 %	36 %
male 'say'	23 %	17 %	24 %	43 %	27 %

coordination impact of JurMOO for the seminar (5.2 to 5.7). One possible interpretation could be, that female students welcomed the more communicative style, whereas male students saw the seminar preparation by JurMOO more as a measure to improve the overall teaching quality of the seminar. The promotion of the mutual understanding regarding what each is doing and learning contributes of course also to the development of an actual learning group, which is one of the big problems of distant education.

Conclusion

Our results regarding the possible convergence of user strategies and the higher female contentment with the mutual understanding support the assertion that the use of a MOO-like tool can be a promising instrument for gender mainstreaming in distant education. The gender gap (regarding in possession/access of, assumed knowledge about, and usage of new media technology) can be smoothed by a systematic integration of communicative and presentational functions, because the changed status of the communicative function directly affects the participation structure and with it the satisfaction of women.

To allow the convergence of these different strategies and the establishment of a learning group sharing its knowledge this technical side has however to fit in an overall didactical setting, where e.g. the incentives have to be tuned in a much more deliberate way than in classroom education. The conditions for (equal) participation in scientific discourse furnished by educational multimedia can be substantial for didactic success, because in this way the contextualization of each owns contribution is provided. So this approach first set by the interest in gender equality fits into the general realm of constructivist learning theory. The fact that men 'adapt' to a more participatory style, if the didactical and technical setting stimulates it, shows the general potential of this approach.

rcarlson@gasou.edu

Abstract: This brief paper provides an overview of successful strategies and policies related to faculty rewards and incentives that promote participation in distance learning. Best practices and suggested strategies related to faculty motivation for e-learning will be presented.

Introduction

In his classic work on the diffusion of innovations, Everett Rogers offers this definition: "*Innovativeness* is the degree to which an individual...is relatively earlier in adopting new ideas than the other members of a system" (1995, p. 22). Rogers goes on to classify adopters into several categories: innovators, who are ahead of the curve; early adopters, who follow innovators and are often seen as opinion leaders within the organization; the early majority, who typically make up about one-third of the members of the system; the late majority, who tend to be skeptical about innovations; and, the laggards, who make decisions based on "the way we've always done it" (1995, p. 261-265).

Many E-learning attendees fall into the categories of innovators and early adopters. You embrace e-learning enthusiastically and lead your organization in creatively applying cutting edge technology in the teaching/learning process. Can you keep going it alone or in small numbers? The answer is probably not. Unless members of the early and late majorities (about two-thirds of the organization) begin to participate in e-learning, your efforts may be marginalized. E-learning will not be seen as part of your organization's mission or vision, nor will its value be recognized or rewarded. Since the participation of the early and late majorities is critical to the success of any innovation, we're going to examine characteristics of these groups. We'll also examine some possible rewards and motivators for higher education using Rogers' diffusion of innovations categories as the framework for the discussion. Those of you in corporate e-learning environments where tenure and its security are traded for other rewards can translate the following arguments to those that are meaningful to your organization.

Motivation

Incentives and rewards are closely related to motivation. Motivation theory supports the notion that incentives don't come in a "one size fits all" model. Intrinsic motivation, when an individual's desire to learn something or do something becomes rewarding in and of itself, is certainly a critical component of adoption of an innovation like e-learning. It plays an important role in the risk-taking behavior exemplified by innovators and early adopters. These groups embrace e-learning because it offers new and different ways to address teaching and learning issues and it promises to improve the efficiency and/or the effectiveness of instruction. Extrinsic motivation has its source external to the individual. Money in its various forms (cash, promotion, time off) is probably the most powerful and common extrinsic motivator.

However, some people are motivated by praise or recognition from their peers or supervisors. In a school setting, grades are the most common extrinsic motivators for students. While members of the early and late majorities may come to feel the same intrinsic motivation to participate in e-learning as time goes on, some kind(s) of extrinsic or external rewards or incentives might need to be used to get the process started (Bower, 2001).

Early and Late Majority Adopters

A large body of research in areas ranging from prescribing new drugs through the spread of educational technologies supports our earlier statement that most members (60-70%) of any group can be classified as early or late majority adopters (Rogers, 1995). The early majority adopters don't want to be the first to try something, nor do they want to be left behind. This group relies on the judgment of people that they consider to be opinion leaders. After observing the behavior of the opinion leaders, the early majority will usually go ahead and give the innovation a try. A little extra support and/or encouragement may be needed for the early majority to move beyond trial to adoption of an innovation. Late majority adopters are more skeptical. They may wait until there is little other choice but to adopt an innovation. Peer pressure may have to be considerable to initiate action (Rogers, 1995). One interesting consideration is that resistance to change is an important part of the natural cycle of the diffusion process. "Even those who approve of an innovation are likely to find some aspect of their cultural or social identity challenged, and some professional or psychological comfort zone intruded upon" (Ellsworth, 2000, p. 166). To be receptive to the value of e-learning, early and late majority adopters must first resist it. Whether or not they get past this resistance phase may depend on the rewards and incentives available. The first area that must be addressed is very basic: Do faculty think that e-learning is relevant to the mission of their organization?

Centrality to Mission

The rapid growth of e-learning has taken many institutions by surprise. Higher education has its fair share of laggards in leadership positions, so it isn't surprising that few institutions specifically mention e-learning, distance learning or distributed learning in their mission statements. Yet it is crucial for members of the early and late majorities to see the link between e-learning and the institution's mission. In a survey of Management faculty, Rahman found that the most important reason given against online teaching was that faculty believed that it was not part of the university's mission (2001). The same study found that e-learning adopters *did* believe that e-learning was part of the university's mission! Centrality to mission is important in building intrinsic motivation for e-learning. If the mission statement doesn't clearly discuss e-learning, Rahman suggests that less direct phrases like "student centered university" and "access" be highlighted as supportive aspects of the mission. Georgetown University's Research, Curriculum, and Development Group page (http://www.georgetown.edu/uis/rcd/index.html) provides an example of a direct link between a university's teaching/learning mission and faculty technology use. No matter how the link is made between the mission and faculty practice, the connect/disconnect becomes overt when faculty try to figure out how the primary reward system (promotion and tenure) accommodates e-learning and faculty development.

The Higher Education Reward System: Promotion and Tenure

While many educational institutions actively seek to hire junior faculty with both the skills and the desire to engage in e-learning, these new roles and responsibilities are not reflected in promotion and tenure policies or guidelines (Wilson, 2001; Young, 2002). One important consideration is the weight given to course development and delivery in promotion and tenure criteria (Prestera & Moller, 2001). Some call this movement "the scholarship of teaching" and suggest that examination of relationships between teaching activities and student performance should be part of the higher education reward system (Bass, 1999; Cambridge, 1999). We don't want to stifle the creativity and energy of faculty who are excited about high-tech possibilities for learning, nor do we want to set them up to fail under the existing system.

Many faculty who are enthusiastic users of instructional technologies still value traditional definitions of research and service. At the same time, the diffusion of e-learning offers many possibilities for faculty and administrators to take part in a dialog about promotion and tenure. Early and late majority adopters may need to have these issues out on the table before they are even willing to try e-learning. If these groups are already hesitant about new technologies, their reluctance will only be reinforced if they feel that the reward system might actually punish them (i.e. denial of promotion and/or tenure).

Many e-learning innovators see themselves as educational entrepreneurs. As noted in the ACE/Educause report *Distributed Education and Its Challenges: An Overview*, "Some faculty may be willing to trade security (i.e. tenure) for greater economic opportunities and payoffs." (2001, p. 13) The entrepreneurial faculty member may not even want to work for an institution where the primary reward system (i.e. promotion and tenure) is based on the face-to-face classroom model of teaching and traditional definitions of research and service. This problem is compounded when many potential early and late majority adopters are untenured and thus at the greatest risk for personal failure in terms of this reward system.

Extrinsic/External Motivators

Promotion and tenure is the most visible extrinsic reward system in higher education. Faculty members who don't earn promotion from assistant to associate professor and tenure in the required 5- or 6-year cycle find themselves looking for their next job. But promotion and tenure aren't the only external motivators around. Three categories of external motivators have been widely used to promote change in higher education: monetary incentives, workload incentives, and training and support.

When 1500 faculty members in Kentucky were surveyed about incentives for distance learning, financial incentives were ranked lowest (Wilson, 2001). Rahman's (2001) study demonstrated the same surprising finding, although in his study junior and adjunct faculty members ranked financial considerations higher than senior faculty. What does this mean to administrators trying to promote e-learning? It means that, unlike the movies, faculty aren't sitting in their offices screaming "Show me the money!" into the telephone. We're sure that most faculty wouldn't turn down money if it is offered, but it does seem that faculty actually consider other factors to be at least as important as money.

Workload considerations do seem to be more important to faculty members, primarily because of the amount of time required to design and deliver instruction using new tools and instructional strategies. Conference presenters demonstrating distance learning modules or courses almost always mention how long the development process took – and if they don't mention it someone in the audience will ask. Casual hallway conversations about on-line courses focus on the amount of time it takes to respond to the flood of student e-mails and threaded group discussions. Common workload incentives include summer grants and release time for course development (Rahman, 2001). Release time may be as little as one course for one semester, which supposedly is adequate to get a course ready for web-based delivery. This release time vanishes once the course is on the web. Given the emphasis placed on publication in refereed journals that is the cornerstone of many promotion and tenure systems, it isn't surprising the early and late majority adopters are reluctant to invest large amounts of time mastering new technologies and reconfiguring courses and student learning activities.

The same faculty surveys report that training and support for e-learning are critical (Rahman, 2001; Wilson, 2001). Bower notes that "fear of appearing incompetent may cause faculty to resist involvement in any activity for which they have not had the proper training" (2001, p. 2). There are many models for faculty support. Some institutions employ teams of instructional designers who will consult with faculty and basically do all of the technical work associated with changing to an on-line format. Other institutions offer group training sessions and individual consultations for faculty members, but the faculty member has the primary responsibility for doing the work. Using students to provide this support is an increasingly popular option.

The University of Central Florida (http://reach.ucf.edu/~coursdev/) offers all of these services through the UCF Course Development and Web Resources Virtual Development Team. This kind of centralized model might not fit the style of all institutions but it does save faculty members from trying to figure out who to call to answer a certain kind of question. Many institutions have adopted approaches recommended by the Teaching, Learning and Technology Group (http://www.tltgroup.org/) to support faculty use of educational technology. Making these kinds of resources available and appealing to early and late majority adopters is critical. Innovators and early adopters need to share their expertise and insight through institutional support systems—even if attendance at workshops, chats, etc is not always high.

Conclusion

As the ACE/Educause report notes, "In an era when many students have never known life without the Internet, when time is constrained for adult learners seeking additional education, and when worldwide demand for education is at an at all-time high, the classroom no longer bounds the learning environment" (2001, p. 2). Many faculty have heard this directive and have acted on it. Now it's time to get other faculty on board, focusing on the early and late majority adopters. Innovators need to fight the tendency to say "nobody paid *me* any extra money or gave me any help when *I* taught my first on-line class" and recognize that external motivators may be needed to move the process along.

Empowerment Through Equitable Access: Middle School Students Developing Strategic Skills In E-Learning Environment

Reynolds, Thomas
National University
USA
treynold@nu.edu

Serdyukov, Peter
National University
USA
pserdyuk@nu.edu

Abstract: Infusing technology in school is successful when it is a convergent process: a technology-based environment is created to provide computer and Internet applications in all classes, and, at the same time, computer or information literacy programs integrate strategic skills with technical skill development. Such a synergetic approach combines practical computer-based assignments in the computer literacy class together with complex intellectual activities. This paper describes such a symbiotic e-Learning project for middle school students.

Information and Computer Technology (ICT) plays a dual role in education: it is the object of learning and, at the same time, a tool for learning. As part of school curriculum, it is intended to help students to master the use of computers and the World Wide Web. This goal is pursued through computer or information literacy programs in schools that assist students in learning how to use contemporary technology. Remarkably, computer literacy in schools is often regarded as a goal in itself and as a particular subject area. However, ICT is also used as a teaching and learning tool in practically all classes and in students' independent work. Computers help to enhance students' learning activities and empower them to solve higher order cognitive tasks. This is why infusing technology in school is successful when it is a mutually beneficial process: on the one hand, a technology-based environment is created to provide computer and Internet applications in all classes, and, at the same time, computer literacy programs integrate strategic skills with technical skill development. Such a synergetic approach combines practical computer-based assignments in the computer literacy class and complex intellectual activities. The students then are engaged in solving cognitive tasks in accordance with K-12 Content Standards (1) while developing basic computer and Internet skills.

The task of teaching computer and information skills together with developing higher order skills is aggravated by limited access to information technologies and Web-based educational resources in schools located in low-income multicultural areas (2). Consequently, it is crucial to provide equitable opportunities for disadvantaged students from these areas to use contemporary educational resources and technologies in order to fully benefit from the mainstream school instruction.

This paper describes an e-Learning project being jointly developed by Marston Middle School, San Diego Unified School District, and National University, La Jolla. In this program that was initiated in 2001, the University professors together with student teachers teach an ethnically and culturally diverse class of 15 students of 12-14 years of age. The class takes place on Saturday mornings and lasts 2.5 hours. The goal of this project is to create a specific e-Learning environment to help diverse school students become computer and Internet literate and, at the same time, develop their cognitive and social skills that will contribute to their mainstream learning. Specific objectives of this project are:

- Build a model of instruction for a symbiotic information literacy and developmental program.
- Implement K-12 Content Standards in a Flexible School Program.
- Help students develop computer and Internet skills.
- Create conditions where students will apply their knowledge and skills acquired in the regular class to real-life problems solved by using ICT.
- Teach students to solve cognitive tasks while learning to use e-Learning tools.
- Bring about positive side effects in reading and writing.
- Develop a collaborative community of learners.
- Train schoolteachers and student teachers to effectively run the program.

The model of learning we are investigating now consists of five steps:

1. Task Setting. A problem is described and the task for students is defined.
2. Model presenting. Students are explained and shown ways to solve the problem using a computer and the Internet. This is where various computer uses are demonstrated and skills taught.
3. Individual work. Individual information search and processing
4. Small group work. Students share the information they collected and created, and collaboratively develop a project.
5. Whole class work. Project presentation and discussion.

In the process of this program implementation, several tasks are being solved: students learn to pose questions, to define intellectual tasks, to find and process online information, to solve problems and develop projects, to work collaboratively in a group, and present their findings to the class.

ICT is explored and applied in its many roles: as a tool for learning, for solving problems, for information search and processing, for electronic computer-mediated communication and as a game machine for developmental purposes.

The students' learning outcomes will be assessed in the end of the year. In the meanwhile, we observe students' evident success in mastering e-Learning tools together with growing interest and motivations for learning. They are able to solve more complicated cognitive tasks today than in the beginning of the year. The next step will be to improve the model and to expand the current effort to include new schools, with concomitant recruitment of both students and teachers.

The importance of this program goes beyond the framework of the current project: our intent is not only to expand it to other schools across the school district, but also to use it in preparing teachers at National University as a practical example of equitable access to education provided for diverse student population through an e-Learning program.

A Multi-Disciplinary Framework for the Design and Evaluation of Computer Supported Learning-Environments

Christoph Richter, Heidrun Allert
Learning Lab Lower Saxony, University of Hanover, Germany
{richter, allert}@learninglab.de

Abstract: This paper outlines a framework for the design and evaluation of information and communication technology in learning environments. This framework is intended to support multidisciplinary cooperation during the entire project lifecycle. In contrast to other approaches it does not merge the distinct approaches but links them via a common communication platform. An extended scenario-based approach is outlined to meet the special requirements for this purpose. The domain specific approaches are interpreted as special views on the common artefact. The framework integrates the design of the social learning environment with the development of adequate technology based support. Additionally, an elaboration of this framework in form of a conceptual toolbox is drafted.

Motivation

We specify a framework for the design and evaluation of information and communication technology in learning situations. This framework has its origin in our experiences in consulting different projects within the Learning Lab Lower Saxony [L3S]. The Learning Lab Lower Saxony is a multidisciplinary research lab that focuses on the development of innovative learning technologies and is a member of the Wallenberg Global Learning Network. Within the L3S the main task of the eTeam (evaluation team) is consulting and coordinating design and evaluation of distributed projects in collaboration with the project members. The concept of theory-based evaluation is guiding this work (Nash, 2001).

Conceptualizing design and evaluation of information and communication technology in learning situations is a multidisciplinary enterprise and is accompanied with specific challenges. While it is often stated that multidisciplinary approaches are crucial in this field, there is a lack of concrete methods to facilitate this cooperation.

The diverse disciplines, which contribute to the development of technology supported learning environments, apply specific methods of modelling, implementing and evaluating domain specific artefacts. These distinct approaches and methods are widely used within each discipline. An approach, which connects these methods is still missing. The framework we present facilitates the combination of the different approaches without losing the specific advantages of each method. To respect each domain specific method facilitates multidisciplinary cooperation.

Problem Description

The following disciplines are mainly involved in the development of technology supported learning environments: computer science, media design, learning science, program evaluation. Within multidisciplinary projects any of these disciplines make unique contributions that cannot be compensated by any other discipline. Beside their distinct focuses every discipline has developed specific methods to model, implement and evaluate the artefacts they produce.

- In computer science various concepts taken from the field of software engineering are widely used. While the Unified Modelling Language (UML) is a common approach to model different aspects of software artefacts, methods such as usability testing are used to assess the artefacts.
- In educational science specific teaching and learning models to design learning environments are in use. Instructional principles such as PBL, Case-Based learning, Competency-Based learning e.g. work as

frameworks for design. Beside this methods of pedagogical evaluation that focus on motivational and instructional aspects e.g. are applied.

- We understand program evaluation as a separate discipline because it provides unique methods for describing projects, ways to guide the development and also provides concepts for assessment and evaluation. For example in theory-based evaluation methods have been developed to describe an evaluand including the views of all stakeholders (Strömdahl & Langerth Zetterman, in process). Program evaluation has been applied in fields as diverse as education, economy, health care, ecopolitics and many more (e.g. Wottawa & Thierau, 1998).

Any of the mentioned disciplines have developed concepts that can be used during the whole project process from planning to a completing summative evaluation of the artefact. But every single approach focuses on domain specific aspects and neglects other. While approaches in the field of software engineering are specialized to support the development of technical systems, they are often unsuitable to describe sociotechnial systems (see e.g. Goguen 1994). On the other hand methods to model educational settings focus on social processes and tend to view technology only from a user perspective. While methods of program evaluation are applicable to support any kind of project they strongly require clear and unambiguous description, which can only be provided by the projects themself.

Towards a Solution: a Scenario-based Communication Platform

While there are attempts to develop approaches specifically addressing the design of technology supported learning environments it has been argued that it is not useful to build a unified framework that subsumes several approaches from distinct disciplines (e.g. Bannon, 1994). In contrast our framework provides a method to explicitly link the already existing domain specific approaches without subsuming them under one theory. We consider any of these domain specific approaches as specific view on the common artefact (the intended educational setting). The crucial point in linking the different views is to establish a communication platform that can be used by any stakeholder. Also it has to be ensured that all stakeholders can translate the joint description of the artefact into their domain specific models.

The scenario-based approach provides this communication platform (see Fig. 1). Scenarios have been used in many different domains. For example in different areas within the Computer Science (e.g. Rolland et al., 1998) as well as for purposes of strategic planning in fields as business, economics, politics (e.g. Kahane, 2000).

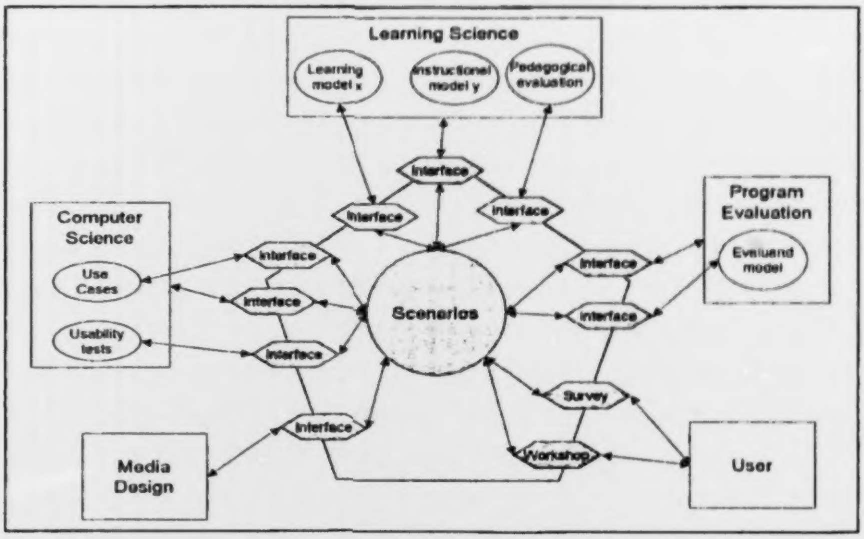

Figure 1: The core elements and interrelations of the *scenario-based communication platform*

BEST COPY AVAILABLE

We refer to the definition of scenarios proposed by Carroll (2000): A scenario is a concrete story about use. Scenarios include protagonists with individual goals or objectives and reflect exemplary sequences of actions and events. This definition is much broader than other definitions of scenarios and more comprehensive than the concept of use cases proposed by Jacobson et al. (2001).

The use of natural language as the basis for the communication platform helps to introduce domain specific knowledge into the discussion on the joint artefact. On the other hand narrative stories can be told on any level of abstraction as well as any level of granularity. Scenarios can also be written and discussed by the end users of the artefact.

In order to use scenarios to link several domain specific design approaches it is necessary to extend existing scenario-based approaches. On the one hand scenarios have mostly been used in projects dealing with work and not with learning. On the other hand scenario-based approaches do not systematically address socio-technical and social aspects of the artefact. Some scenario-based approaches (e.g. Benner et al. 1993; Kyng, 1995) actually broaden the scope, but do stress the importance the context in general and lack a definition of context. Those, which provide a well elaborated framework focus on work.

The core elements and interrelations of the *scenario-based communication platform* are illustrated in Fig 1. The elements in the domain-specific boxes represent some examples. The domain-specific concepts are related to the shared scenarios via interfaces. In this context an interface is a specific method that allows to transform domain-specific concepts into scenarios and vice versa. Some of these interfaces have already been outlined. Carroll (2000) describes how to link scenarios and use cases. Bødker et al. (1995) have developed a work-oriented checklist that helps to identify and reflect about core aspects of a concrete work situation described in a scenario. While this checklist links the sociological CSCW literature to scenarios similar checklists to link instructional models to scenarios are conceivable. We also recognize a lack of interfaces between scenarios and program evaluation. The interfaces to the user are formed by surveys, workshops or other methods that help to reveal the users point.

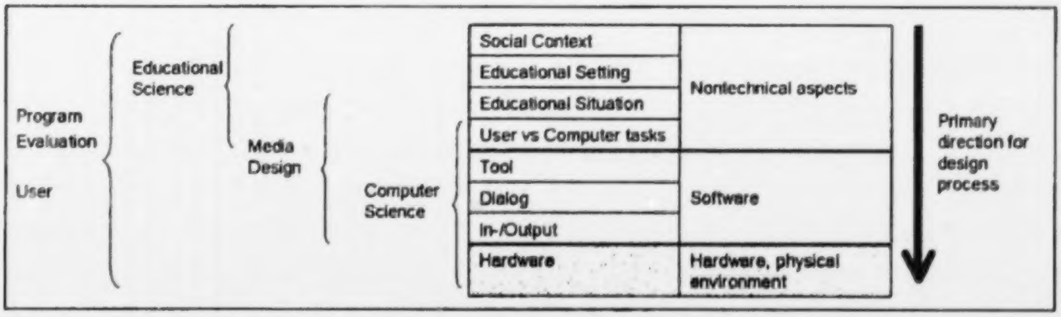

Figure 2: levels of granularity (based on a diagram by Koch et al. 1991, p. 30)

Scenarios, which are concrete stories of human activities, can be told on different levels of granularity. Fig. 2 lists 8 levels that are relevant to the design of technology supported learning environments. According to Koch et al (1991) we presume that the design of computer supported systems has to start on the social and organizational levels. Later within the progress of the project, scenarios also address the technology that supports learning and teaching. This does not eliminate the necessity to reflect on the social effects evoked by the technology. This proceeding does ensure that technology supports the learning situation and not vice versa. Fig. 2 also shows that the different groups of stakeholders with their different views on the learning situation contribute at different layers. As a consequence of this not all stakeholders are involved during the whole process to the same degree. A typical problem we are confronted with: At the beginning of a project the computer scientist does not realize what the learning scientist focusses on. Later the learning scientist cannot estimate whether the implementation the computer scientists works on does exactly meet the requirements of the proposed learning environment.

Conclusion and Further Work

The proposed framework provides several advantages compared to approaches that try to merge different domain specific methods. The use of a common communication platform and interfaces enables all stakeholders

BEST COPY AVAILABLE

to use their domain specific methods without modification. This helps to conserve the unique advantages of the different methods and enables multidisciplinary cooperation at the same time. The framework is useful to develop sophisticated evaluation strategies, which can combine a broader range of variables, survey methods and data. Therefore this approach facilitates the concept of triangulation, called for in the field of evaluation and empirical research methodology (see e.g. Worthen et al. 1997; Mayring 2002). Understanding the design and evaluation of educational settings as a multidisciplinary challenge reflects the complexity of this task.

At the moment we already use scenarios in consulting several projects at different stages of the project lifecycle. Our next step will design, apply and evaluate a conceptual toolbox for the design and evaluation of educational settings supported by technology. The tools are intended to support projects but also provide a framework for those who consult projects. Basic tools will describe and facilitate the writing and management of scenarios at the centre of the communication platform. Further tools will form the interfaces: we will draw into account already existing methods, like workshops, checklists etc. but also design completely new methods. For example: The interfaces of learning science will provide prototypical scenarios, which explicitly represent specific instructional models, learning theories and paradigms. These scenarios will correspond to several sets of educational metadata. These sets of metadata will explicitly model learning paradigms, principles and theories and therefore allow to share and re-use conceptual structures. On the other hand this interface will support consulting: often projects state a specific learning theory or learning paradigm (constructivism e.g.), but do not actually address it in their design. Scenarios help to discuss the relevant aspects.

Furthermore we will create interfaces that link the scenarios with program evaluation. These interfaces will support the design of appropriate evaluation plans. The results of evaluation provide feedback to all stakeholders and help to refine the existing scenarios.

Inclusive Workforce Development in an *E*-learning World

Creating a Fully Inclusive Twenty First Century Workforce System

> *(For workforce development programs and their business customers), e-learning holds the potential of contributing to significant gains in worker skills, productivity and performance. E-learning also can deliver significant cost savings when compared to traditional types of (workforce) training. Equally important, e-learning can provide access to high-quality training content from countless sources throughout the world. This, in turn, can lead to improvements in individual and organizational performance. (For workforce communities) e-learning's promise rests in its potential as a driver of value-added economic growth. By opening the door to dramatic boosts in business performance, productivity and the number of skilled workers, e-learning can play an essential role in economic development initiatives at all levels. (For individual citizens), e-learning can broaden opportunities for skill development and employment in high-quality jobs for all segments of the population, contributing to income growth, improved lives for Americans, and a more informed and contributing citizenry. A Vision of E-Learning for America's Workforce, Commission on Technology and Adult Learning (2001)*

Lessons Learned

We have recently completed a century and a millennium. Our Old World in the twenty-century has come to an end and a new world is upon us. We now relate differently, play differently, learn differently and work differently than our parents. While this is true for most of us, many are still stuck in the twentieth century depending on an old world workforce system. "The world is fast polarizing into two potentially irreconcilable forces: on one side, an information elite that controls and manages the high-tech global economy; and on the other, the growing numbers of permanently displaced workers, who have few prospects and little hope for meaningful employment in an increasingly automated world"[i]

"Just as e-learning presents a number of opportunities for individuals, organizations and society, it also poses some serious questions for the future, including: How do we ensure consumer protection and high-quality learning in an open e-learning environment? In a learner-centered system, what is the best way to assess what individuals are actually learning? How can we best certify learning results? And how do we promote equitable access to the technologies and the high-quality.[ii]" The digital divide is one of the most important civil rights issues facing our modern information economy. As telecommunications increasingly entwines itself with educational, social, financial, and employment opportunities, those workforce communities lacking access will find themselves falling further behind the rest of society. The Internet has the potential to empower its users with new skills, new perspectives, new freedoms, even new voices; those groups and communities who remain sequestered from the technology will be further segregated into the periphery of public life.[iii]

Within this group of permanently displaced workers are most individuals with disabilities, as employment continues to be the area with the widest gulf between those who are disabled and those who are not, with nearly 2/3 of those that want to work unable to gain access to employment. (Harris, 1986, 1994, 1998 and

2000.) Accessibility problems have increased dramatically with new developments in hardware, software and Web page design. With limited access to the information superhighway, those who could benefit the most are being overlooked.

Workplace diversity is increasingly recognized as an organizational asset. Many companies operate in global markets, and a diverse work-force is more capable of serving a diverse customer base. Moreover, in industries and workplaces that thrive on creativity and innovation, a diverse work force produces different perspectives, different approaches to solving problems, and a richer pool of ideas. As we enter the 21st century, according to the Department of Commerce Office of the Technology Policy, two-thirds of new work force entrants will be women and minorities. Yet, today, women and some minorities including people with disabilities are underrepresented in the technical work force. This outcome partly originates in the current workforce development pipeline.[iv]

During the past decade, university and private entrepreneurs have invested tens of million of dollars and ten of thousands of hours to plan, promote and deliver Web-based and related forms of distance education. Yet, often these initiatives move forward as if it was something new, a kind of unintended consequence of the Internet. While technology, specifically e-learning has raised the aspirations for more automated online workforce development opportunities, the current economic downturn appears to be producing significant on-line enrollment downturns at many educational institutions and a number of dot-com education providers have simply vanished, thus providing early important e-learning development lessons.[v]

First among these lessons is that anytime anywhere e-learning really can expand learning opportunities by mixing convenient access with enhanced, effective customized multimedia content. However, contrary to popular consensus, the next learned lesson is that content is not king, and in absences of a supportive facilitator and an appropriate enabling infrastructure, content has little value. Learning is still change, and people only change when they have to change, when the pain of learning becomes less than the pain of maintaining the status quo. Up to 75% of e-learners drop out of non-instructor facilitated courses before completing them, reports Gerard Prendergast.[vi]. "It's the tutoring processes that will determine whether people complete their learning experience successfully," he concludes. Trained tutors also provide a crucial intangible – encouragement, especially for those lacking even basic computer literacy skills that are more likely to served by a one stop center.. He also claims that with trained tutors, the dropout rate in his study of corporate e-learners was reduced from 75 to 8 percent. Mix these trained tutors with high quality, engaging, customized, and validated e-learning content that is easy to view and read, along with high speed Internet connections and computers; and a model for a next generation workforce lifelong learning system begins to emerge.

A Next Generation Workforce Development System Vision

> *I have learned about two ways to think about technology: one is called automating, the other is called informating. One will give you incremental improvement; the other will give you big improvement. Unfortunately training programs and technology tend to focus on automating. The means that you bolt technology on top of what you are already doing... You get very different results when you informate. The real revolution is information and communication, not technology. Let go of the word technology. If you focus on it, then you'll just do what you're already doing. The trick in planning as we move forward is to think about (workforce) information systems, whole systems of the flow of information and communication — Alan November -from Creating a New Culture of Teaching and Learning.*

Most one stop workforce centers are now taking that first step in getting wired, but they must also consider the needs of the learners, the teachers, and the communities that support them. Access, content, literacy, pedagogy and community—may not be enough to complete the entire digital divide puzzle, but they go a long way in providing a picture of what is at stake. What is needed is a dynamic e-learning culture that embraces the inherent contribution of all people as life-long learners to meet the needs of both the individual and society. Not only do dynamic e-Learning cultures need to address personal, community, and organizational aspects of learning – they also have to attend holistically to what best influences learning for individual learners given the particular knowledge and skill areas being developed. For the optimal development of positive e-learning contexts and cultures, attention is needed to research validated principles that can meet the learning needs of all learners. New roles for workforce center administrators, teachers or learning facilitators, and students must be considered. Envision that traditional concepts will be abandoned as all become learners and interchange roles from learner to expert learner.

Leaders will need adaptive expertise and political leadership to evolve new forms of assessment and accountability in dynamic e-learning cultures. Effective assessment and evaluation practices need to hold workforce training programs accountable for customizing e-learning using activities based on individualized e-learning plans implemented in a workforce community context. Private sector developers are spending millions of dollars to optimize e-learning systems. The workforce system needs to develop private sector partnerships to ensure that universal design principles are incorporated in all next generation learning systems as well as to validate these system with a diverse array of adult learners. Accountability policies for training and job placement, assessment and evaluation practices aligned with core standards and indicators, funding criteria, and articulated outcomes that are balanced for individual and societal needs are required.

> *Issues of learner achievement cannot be separated from issues of teacher expertise, professional development, prevention and intervention strategies, curricular alignment, assessment strategies, leadership, and funding. To be successful, efforts must include changes in all of these areas. It is one thing to embrace the idea that all can learn; it is another thing to make sure they do learn. –from Blueprint for Student Success*

An NSF sponsored study at Western Michigan University evaluating the use of Smart*Force* e learning with students with disabilities attending community colleges is being conducted. The current e-learning market leader is Smart*Force* with over 1.5 million online learners world wide including much of the U.S. military provides 24/7 online live mentoring support to supplement an extensive learning management system (LMS). Early results seem to support Prendergast's claim on the importance of trained tutors in the e-learning process. Customers of second chance programs within Workforce system can especially be expected to benefit from the personal encouragement that a 24x7 trained tutor can provide while using a comprehensive, customizable e-learning management system like that being developed by Smart*Force*.

Recommendations

1. Promote, quality e-learning experiences including the provision of appropriate infrastructure, accessible learning environments, support systems and trained tutors to use with corporate quality e-learning management systems that are both customizable and comprehensive.

2. Create an e-learning workforce culture that supports student motivation, learning, and achievement while also supporting the teacher's (tutor) need to also be a learner.

3. Pursue healthy e-learning networked communities that works for everyone, and encourages rather than eliminates diverse perspectives.

4. Provide the tools and capacity for networked workforce learning communities that can expand and transform notions of e-learning in ways that produce healthy and productive lifelong learners within a larger integrated networked community of learners.

5. Provide new approaches for measuring, certifying and reporting on authentic e-learning outcomes.

6. Ensure equitable access to e-learning opportunities that are available and known to all.

7. Pursue public - private sector partnerships to conduct research and development on how adults learn and how to measure adult learning in meaningful ways.

8. Advocate to all that even the most advanced technology-supported networked learning communities need to be supplemental to the human elements of insight, understanding and encouragement provided by trained tutors (instructors) engaged with the learner in a guided partner relationship. Such a relationship must allow the learner to take ownership of their own career development plans by making informed choices and the taking responsibility for reaching and resetting their careers goals in this brave new e-learning world. A Multi-Dimensional Project to Assess Student Information Competence Skills

Ilene F. Rockman and Gordon W. Smith
Division of Information Technology Services
Systemwide Library Services
Office of the Chancellor
The California State University
United State
irockman@calstate.edu
gwsmith@calstate.edu

Abstract: As librarians and faculty work together to integrate information literacy into course offerings, an area often overlooked is assessment. When evaluation methods are used, they tend to be campus-based and quantitative in nature. The California State University (the largest system of undergraduate higher education in the United States) has recently undertaken a multi-campus, multi-year, and multi-dimensional project to assess student information competence, especially in this current technologically rich and complex distributed learning environment. Results have wide-ranging implications for the design of library portals, gateways to information, and web-based retrieval tools. In addition, results show the need for librarians and faculty to collaborate to teach students how to find and critically evaluate information, and to become more aware of the wide range of information formats available.

Introduction

As distributed learning technologies permeate higher education, librarians find themselves providing an increased number of technologically-based services for students who cannot, or choose not to, come to the traditional library. Remote access to subscription-based databases and electronic books, information tutorials for distant learners, and virtual reference services are just some of the examples of services which have been offered by academic libraries during the past several years.

Librarians, working closely with faculty members, have also recognized the importance of teaching information literacy skills in this rapidly changing, complex information environment. Although students may be facile with sending e-mail, downloading music, developing a web page, or watching a streamed video, students are entering our colleges and universities with uneven skills and abilities in finding, evaluating, managing, and ethically using information resources in all of its various formats, critical skills for academic success and lifelong learning in the 21st century.

Nationally, reports indicate that "less than half (48 percent) of students feel confident in their ability to find information—essentially, in the skills needed to research a topic" (National Center for Postsecondary Improvement, 2001, p. 29). In one recent study, "based on their library website experiences, over half of the students (55%) report having a difficult time finding complete articles that include charts, tables, and photographs." (OCLC, 2002, p. 7). In addition, "when asked to describe problems and drawbacks they face when looking for information, end users consistently describe a number of factors: knowing what information is available, determining the quality/credibility/accuracy of information, information is too hard to find, being able to compare across information alternatives, having sufficient training". (Outsell, 2001, p. 5).

These studies support the need to assess information competence skills of students, and to recommend strategies for overcoming deficiencies.

For the past several years, The California State University system (the largest and most diverse system of higher education in the United States, serving over 388,000 students on 23 campuses) has undertaken a multi-campus, multi-year, and multi-dimensional research project to assess the information competence skills of its undergraduate students. This paper will report on the goals, methodology, and results of the project.

Background

In 1994, the California State University (CSU) Council of Library Directors created a strategic plan, *Transforming CSU Libraries For The 21st Century* (1994). A key component of that plan was information competence, with the twin goals of (1) providing CSU students with instruction and assistance enabling them to use recorded knowledge and information as an integral part of their university education and (2) collaborating with CSU faculty to provide training and assistance in the use of recorded knowledge and information necessary for their teaching and scholarship.

A key strategy for accomplishing the goals was the establishment of basic competence levels in the use of recorded knowledge and information, and processes for assessment of the competence. In order to carry out this strategy, a CSU Information Competence Work Group was established in 1995 composed of faculty members, administrators, and librarians. Its charge was to develop an information competence program for the CSU. In turn, the Work Group created an Assessment Task Force in 1998 comprised of librarians and faculty. The Task Force ultimately engaged the services of the Social and Behavioral Research Institute located at CSU San Marcos to assist in the design and execution of a multi-dimensional, multi-campus, and multi-year assessment project.

Goals

Utilizing the expertise of faculty members, librarians, assessment coordinators, ethnographers, and social and behavioral scientists, a multi-dimensional, multi-campus, and multi-year research strategy was developed. The goals of Phase I of the assessment strategy were to establish a baseline of student information competence based upon a standard series of questions. Phase II goals focused on student performance or information-seeking behavior to answer the question, "how do students search for information"?

Methodology

Phase I of the study employed quantitative research methods. In Spring 2000, 3309 students (drawn from a random sample) were surveyed to acquire aggregate data to suggest a baseline of students' information competence skills via an originally created questionnaire, based on scenarios, delivered by trained telephone interviewers. The high response rate (77.7%) yielded an average interview length of 24.76 minutes. Results showed that while students do use the Internet as a common source of information, other resources (such as books, reference works, and individuals) are also used.

Phase II, conducted a year later in Spring 2001, was more qualitative and complex. Intended to capture what students do when they search for information, seventy-six students from various CSU campuses were randomly selected to participate in an all day assessment activity on one of four CSU campuses (Fullerton, Northridge, Sacramento, or San Jose). They were compensated for their transportation and their time, and were accompanied by 20 librarians and 10 faculty members. The students were presented with one of four scenarios, and given free reign to use any resources available to them in the campus libraries, including assistance from reference librarians.

A variety of qualitative assessment methods were employed including direct observation, screen capture software, video and audio taped interviews, recording of ethnographic field notes, and focus groups. These methods were intended to shed light on how students formulate a research query, look for information using technology-based retrieval systems, and evaluate the appropriateness of what they find—all key factors in determining information competence.

Results

Results of the Phase I and II research projects show that students frequently use the World Wide Web as an initial step in pursuing answers to questions. In addition, results from Phase II indicate that (l) the online environment influences the way students search for information, and that students tend to over-value current information found on the world wide web over in-depth treatments often found in books and journal articles (whether electronically or print-based), providing them with a false sense of success and misplaced confidence in their search results; (2) students embrace the virtual library for its convenience, flexibility, timeliness, and access to large amounts of information; and (3) although technology makes some information more accessible and convenient to use, it may also limit (or telescope) the information which students actually retrieve.

The results have wide ranging implications for the design of library portals, information gateways, and web-based retrieval tools with embedded, point-of-use instruction.

In addition, the results reinforce the need for faculty and librarians to work together to (l) design course assignments and learning outcomes throughout the curriculum which will reinforce the development of students' information competence skills and abilities (2) teach students how to find, apply, ethically use, and critically evaluate information resources (3) assist students to become more aware of , and the differences between, the wide range of information choices and formats available to them and (4) help students to become successful, self-directed learners.

Virtual Community of Teachers in Switzerland – Are Teachers Ready to Share Online?

Andreas Röllinghoff, Andreas Ninck
Learning Lab, Berne University of Applied Sciences
Morgartenstr. 2c, CH-3014 Bern, Switzerland
[ninck, rollinghoff]@hta-be.bfh.ch
http://www.fnl.ch

Abstract: Educational institutions are becoming more and more aware of the gap between the huge potential of new learning technologies, and their modest application in the classroom. As an answer to this situation, the seven Swiss Universities of Applied Sciences have set up a joint initiative called Forum New Learning, with the main purpose of enhancing knowledge and expertise in new learning technologies for a broader group of interested teachers. This initiative creates the framework for a network of competence among teachers as a 'community of practice'. Members consult and teach each others. They act as learners in areas where they need training, or act as teachers in areas where they possess competence useful to others in the community.

Keywords: Promotion of New Learning Technologies, Virtual Community of Practice for Teachers, Virtual Learning Community among Teachers, Knowledge Sharing, Distributed Faculty Support, Learning Organisations

Introduction

First, the short answer to the question asked in the title: The extent to which most teachers and faculty members are ready to share their knowledge or products in a virtual community is nearly zero. But similar to existing local communities the little percentage of people that do participate actively, is capable of bringing the community to life. They create – in time - a rather comprehensive wealth of material and discussions covering most of the questions and subjects concerned provided that there is a dedicated moderation of the community.

The (not so) long answer follows now. After the obvious success of communities such as *AskMe* (www.askme.com), *PhotoNet* (www.photo.net) and Linux the obvious question was: will teachers be willing to do the same? Our analysis of existing types of communities helped us learn to distinguish between communities of clients, from communities of interest, communities of practice, employee knowledge networks or communities of learners, etc. We visited a number of initiatives on the Web aimed at teachers such as *Virtual Learning Space* (itlearningspace-scot.ac.uk) and *Education with New Technologies Networked Learning Community* (learnweb.harvard.edu) at Harvard, etc., which each differ in aim, scope and especially the extent to which their moderation reaches out to each member. This helped us to define our own objectives.

Mission: Teaching with Technology

Our initiative started with the insight that teachers who are new to online course authoring are considerably hampered in their effort to go virtual, by questions such as: What is the adequate software? How do students learn online? They often hardly know what the potential benefits of the New Learning Technologies (NLT) could be, and how much effort is required to implement some useful and pedagogically effective learning scenarios. More over they have great difficulty finding training or counselling in faculty support that is adapted to their situation. Nevertheless there are a number of teachers who are motivated to use NLT in their courses. How can their efforts be supported? In consequence and in analogy with a professional association our initiative aimed for a virtual community of practice. This community would organise faculty members and provide services such as training, help members to come together to exchange their knowledge and learn from each other, eventually try to define a standard of quality, and most of all collect the state of the art knowledge - but online.

Reaching the Members

To start building a community presupposes that you can reach the persons who might be interested. Some experts advise to start with a newsletter. It seems that another possibility to reach a growing number of prospective members is by giving courses. This was done in our case by giving training workshops all over Switzerland through the Swiss Universities of Applied Science (UAS) training centre 'Didactical Cycle of Ongoing Formation' based in the UAS Freiburg under the heading 'New Learning Technology'. After the courses we invited the participants to share their developing expertise, their experience, questions and problems in a password protected environment. In the absence of a better solution we chose a WebCT course platform (www.webct.com) for this purpose. To give people a reason to go there we placed all of the material that we produced for our workshops into this environment that we called 'FNL-Community and decided to actively animate the Forum through a moderator. This moderator then frequently posted messages, gave information and answered questions that the few participants had placed in the forum. Next we formulated a research project in the framework of the SVC in the UAS with the aim to support teachers of the UAS using new Learning Technologies. When the project was accepted into the larger program 'Swiss Virtual Campus' (cf. http://www.virtualcampus.ch) we integrated the community into the project that we named 'Forum New Learning' (FNL) (cf. http://www.fnl.ch). This began in December 2000 with a head start of 40 members, a number of core information pages, a functioning (though awkward) platform with a forum and a data bank and most importantly the money to pay for a technician, translation and the moderation.

Apart from the platform WebCT, the FNL-Community is also supported by a Web portal, a collaborating team of scientific specialists in 5 UAS and three language regions in Switzerland and by regularly held face-to- face workshops. Members can organise their learning individually, yet share their insights collectively with their peers. In contrast to comparable traditional institutions, the service and counselling is not carried out by a geographically central office, but through a distributed network of persons, which consists of an avant-garde of teachers who have already, or are just starting to build specific knowledge in the field of NLT. These pioneers use the community as a network of competence, with the main purpose to instruct and motivate a broader group of interested teachers to gradually build a generalised competence in the use of NLT.

Virtual Community as Faculty Support

The present state after 20 months. About 200 German and French speaking teachers – have been using a shared file data base and communicate within a forum of a specially -designed course platform.

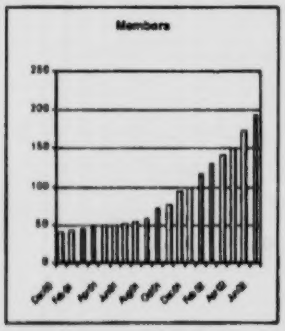

Figure 1. Development of number of members.

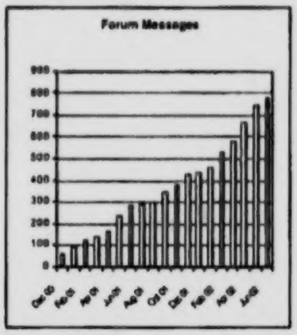

Figure 2. Development of number of messages

- About 300 documents provide training as well as hints and tips for areas such as the use of the WebCT platform, the design of online learning materials, and related pedagogical questions.
- About 800 messages have been posted in the electronic discussion forum by members debating the technical and pedagogical problems they have encountered in their online courses.
- A FAQ gives access to the main technical questions that have been discussed in the first 14 months.

- Course materials have been contributed by the members in 4 areas:
  - online learning activities
  - presentation of learning materials
  - online project learning
  - scientific publications, articles, training material etc.

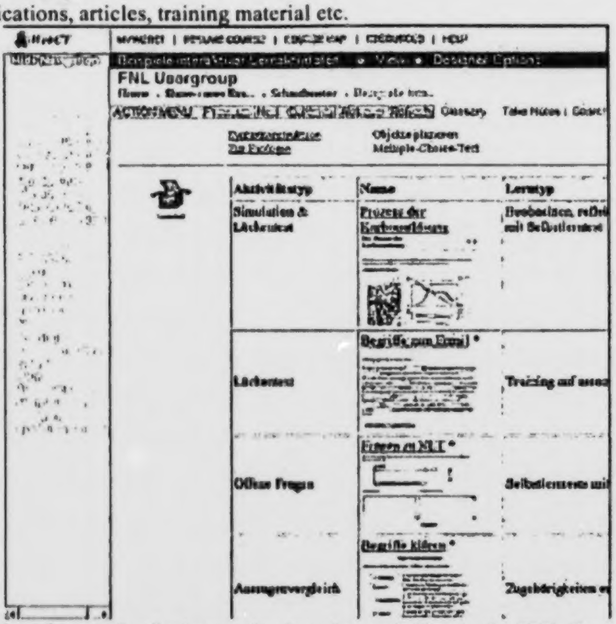

Figure 3. List of examples for interactive learning activities in the FNL-Community

- The differentiation of competencies among members is under way and noticeable. Some teaching-subject related groups are formed for mathematics and language teachers. Others have become the person of reference for specific competencies such as the use of tests or 'streaming video'. Some members have started to volunteer as assistant moderators in sub-divisions of the discussion forum and in workshops.

Interpretation of Some Developments

What is written and how:
Only 147 (73%) from 201 enrolled persons have ever actually entered the Community . Many of these have not posted any or only one message in the forum. Only 26 members have contributed 4 or more messages, 10 of these have sent 10 or more messages.
Many messages are simple requests for information or reactions. This indicates a learning of a practical type. Only very few forum initiatives, 15 out of 125 in the last 6 months, have led to discussion threads with more than 5 replies, thus allowing for a 'deeper' learning process, e.g. a change in pedagogical convictions. The percentage of these longer threads that have been initiated by the moderator has dropped in 6 month from 66 % to 26%. More members have become self- initiating.

What is read:
In the first three months of the FNL-Community most reading concerned technical matters. With the appearance of more pedagogical and didactical material these have reached – after a year - the same popularity. Today the most read texts concern pedagogical and didactical material as indicated by their higher hit rate.

How material is shared:

BEST COPY AVAILABLE

- Overall 19 members contributed learning material or elaborated teaching ideas outside the forum. These have been 'published' in the data bank and are accessible under 'Learning Objects' and 'Show cases'. It is noteworthy though that only 4 of them did so unsolicited. As the contributors need to make a supplementary effort to explain the use of this material to other teachers, this - seemingly - has a limiting effect on the sharing process!

Outlook

The FNL-Community of Practice' has also become a 'Community of Learners'. It has progressed from a practical solutions swap-shop to a platform allowing for broader exchange, including methodological aspects of pedagogy and didactics. To become a valuable learning community, on an academic level, the community will have to lift its intellectual attractiveness by providing a framework for higher level exchanges and profounder learning events. It will nevertheless continue its basic service of practical solutions in technical and methodological matters. To manage this,

- more information has to be gained about the way the community is used by the members. A survey is under preparation to research members' needs and suggestions.
- more (active) members have to be won. We therefore will publish most of the actual password protected content to convince a larger public of the quality of our material, and also simplify the login procedure.
- and to make the usergroup more accessible, a more community-adequate software will soon replace the current clumsy platform. This will provide members with modern community management features such as events reporting, profiling, interface adaptable to users needs etc.
- a higher degree of involvement among the members must be reached as a basis for more voluntary commitment as assistant moderators or material contributors. We will experiment with a new type of meeting with revolving partners in small working groups.

The first results are encouraging. A reinforcing loop has been set up, where teachers are not only taught about new learning technologies, but where they also return a lot of practical and didactical knowledge, feeding the knowledge bases used for their own learning. This process is still heavily subsidized through the FNL. However as the number of active members increases an acceptable ratio of financial input to learning result should be reached before the end of the project in 2003.

Gyrus: An E-Environment for Faculty Development and Student Learning

Teams of educators and technologists at universities around the globe have been seeking solutions to the various challenges posed by the new technologies. One such team of faculty from Santa Barbara City College and the University of California, Santa Barbara have created a course development system called Gyrus and two supporting hubs. The course development environment of Gyrus is designed as a plug-in to Macromedia's Dreamweaver <www.gyrus.nu>. It assists faculty in creating pedagogically sound online courses and course materials. The Gyrus teacher hub has an online syllabus maker <www.teacherhub.org and the student hub is an online student learning environment <www.studenthub.org>. The latter can be used independently by students or integrated into lessons and assignments by faculty using the Gyrus course development areas. All courses and instructional materials created using Gyrus and its hub sites can be used in conjunction with face-to-face classes, local server sites, or commercial online delivery systems.

As a courseware production environment, Gyrus integrates research-informed pedagogy with technology-based instructional methods designed to increase student involvement, independence, and success through active learning, reflection, and metacognition. Gyrus provides faculty with pedagogical resources, including templates and guided instructional processes incorporating "best practices." Its tool sets accelerate content production by helping authors systematically plan and evaluate their instruction, both online and on campus. Guided processes assist faculty in creating syllabi, interactive lectures, and multi-media assignments. Learning skill templates make it quick and easy for faculty to assign skill building assignments that will assist students in learning course content.

Gyrus's Instructional Principles:

The underlying framework of Gyrus as an course design tool is the PIE Principle. That is, designing instruction is an iterative process involving planning three aspects: Planning, Implementation, and Evaluation (PIE). These three aspects of instruction inform one another as the instructor "moves" back and forth between them to complete an effective lesson. While most faculty will readily see the logic of this, the implications for preparing online instruction can be very interesting. Gyrus' environment for creating assignments strongly encourages the faculty author to consider all three aspects of each assignment during the initial planning of any course.

Gyrus' Resource Browser:

In addition to the teaching ideas embedded in the framework of Gyrus, (e.g., tools templates, and guided processes), an online information center assists faculty as they develop course and assignments. It consists of three areas: Student Success Resources that Santa Barbara City College faculty have been gathering as "best teaching practices" for student success and have made them available via the Web; Study Skill Resources offering modules that faculty can send to their students (individually or as groups); and information on teaching topics such as learning styles, communicating with difficult students, teaching styles, and tips for new faculty.

Gyrus' Student Learning Environment:

Gyrus also consists of online learning resources, tutorials, and guided processes that students can use independently or faculty can integrate into lessons and assignments <www.studenthub.org>. It is often the case that students don't understand the intricacies of what is meant when then are asked to compare and contract ideas, summarize articles they have read, or write a report using authoritative Internet sites. At the StudentHub, students find information and guided processes on these and other skills. The searchable site offers a study environment that seeks to assist students in increasing their academic knowledge and skills while helping them to learn how to learn.

An Evaluation of Gyrus' Effectiveness:

Gyrus was developed through a grant by the Fund for the Improvement of Postsecondary Education. As a pilot project it was used in three California community colleges on a limited basis. Results of a two-year evaluation are as follows:

1. Grades assigned to students in course sections that used Gyrus-authored assignments were significantly higher than grades assigned to students in sections of the same courses taught by the same faculty members before or concurrent with their exposure to Gyrus. Persistence too was higher in these sections.

2. Participating faculty reported that exposure to the pedagogical aspects of Gyrus, through both the hands-on training and the system itself, positively affected the way they conceived, prepared, and offered instruction in all their classes, both on-line and on campus. They viewed it as an important source of professional development and reported it as improving their pedagogical skills.

Conclusion: These results are encouraging and suggest that pedagogical tools provided in Gyrus (i.e., teaching skill resources, assignment templates, learning skill templates, pre-made student study skill assignments and skill building exercises) serve to promote both faculty development and student learning. Commercial venders who create course delivery systems are only just beginning to add pedagogical resources for course development. However, none have yet incorporated the kind of assignment makers and guided process the Gyrus provides. Gyrus results indicate that this would be a productive direction for course development software and e-learning delivery systems.

The Concord E-Learning Model

Raymond M. Rose
Concord Consortium
United States of America
ray@concord.org

Abstract: Since 1995, the Concord Consortium has pioneered online instruction. Over the years we have developed and refined the Concord Consortium e-Learning Model for the design and operation of online courses. Using this model, we have delivered over 200 successful courses reaching more than ten thousand teachers, students, and online course developers. Our approach is based on collaborative learning in asynchronous groups guided by trained facilitators.

First, what exactly is an online course? It's a course delivered over the Internet, but that definition—rudimentary, although accurate—is insufficient. The type of online course that The Concord Consortium feels are most effective is one in which there are clearly written assignments that engage the students in active learning with each other, and in which the instructor, plays an integral role as a facilitator of that learning. The Internet is used both as a resource and as a means for connecting particpants based on mutual interest in the content—regardless of individual schedules, geographic location, or physical ability to come to class.

Since 1995, the Concord Consortium has pioneered online instruction. Over the years we have developed and refined the Concord Consortium e-Learning Model for the design and operation of online courses. Using this model, we have delivered over 200 successful courses reaching more than ten thousand teachers, students, and online course developers. Our approach is based on collaborative learning in asynchronous groups guided by trained facilitators.

The type of online course we create is one in which instructor and students will communicate and collaborate on a regular basis. Within the course, students will assess their own growth and learning through group discussion and reflection, peer review, instructor feedback, and self-evaluation. The richness of these interactions will translate into positive and meaningful learning experiences for the students that will carry over into their face-to-face lives.

The following nine key characteristics define The Concord Consortium's approach to delivering quality e-Learning.

Asynchronous collaboration. Participants don't have to be logged on to the course simultaneously; they work in an asynchronous environment in which text-based, threaded discussion and collaborative problem solving form the core learning strategy. Compared to synchronous tools (chats, shared whiteboards, shared applications, and audio conferencing), these asynchronous discussion groups are less expensive, more thoughtful, and far easier to schedule, particularly across time zones. This means that participants can explore the curriculum at their own pace, taking time to reflect carefully and record their thinking.

Explicit schedules. Instructors of online courses relying on collaborative discussions schedule lessons within a specific timeframe so participants can share similar experiences and insights. One major topic provides the focus for the week, with a sequence of activities, discussion, and reflection. For instance, if the content of a video is essential for an upcoming discussion, then the schedule must specify that everyone view the video clip sometime within a few days prior to the discussion. Each participant is then required to make an initial contribution to the discussion. Over the next few days, participants respond to the comments already posted. The best schedule preserves the "anytime, anywhere" flexibility of online courses, while also ensuring that all participants bring similar experience and currency to the discussion.

Expert facilitation. Online courses are led by a qualified person specifically trained in online facilitation. Leading an online discussion is a skill that is learned; it is not sufficient to simply assign an online course to even a highly respected classroom teacher. Teaching strategies that work well in a brick and mortar classroom can have unintended effects online, halting rather than deepening dialogue and learning. Like a good teacher in a traditional classroom, the expert facilitator doesn't ask all the questions or provide too many answers. However, effective online community leaders use many other strategies to stimulate student exchange and guide the conversation toward important content, intervening in discussions only when it serves to move the group more clearly toward learning objectives.

Inquiry pedagogy. Designers create effective online courses with many specific elements that contribute to sound pedagogy for inquiry learning. Graphics, simulations, and role-plays, if used effectively, help learners explore and make sense of content. Course objectives are explicit and matched to the measures used in qualitative assessments. Instructors establish a clear set of rubrics for postings to ensure that evidence of learning is embedded in the discussions.

Community building. Learning through collaboration requires participants to take intellectual risks. It is the responsibility of course designers and instructors to proactively design and nurture a community culture in which participants are supportive and honest. The facilitator establishes and shapes intellectual and emotional norms, modeling appropriate behavior and steering harmful input toward higher learning ground for all. There are many ways to foster this sense of intellectual trust and safety. Providing class time for participants to become acquainted is an essential first step. This is achieved by leading fun ice-breaking activities in the beginning of the course and sustaining a social life for the group with a café or student lounge discussion thread where non-course topics are welcome throughout the course. Written expectations about good group processes are also helpful. For example, instructors encourage participants to use inclusive and collective language that focuses on content in discussion posts. Anonymous polls, role playing, use of smaller discussion groups with rotating roles, or weekly online meetings are all effective techniques for building and maintaining group cohesion.

Limited enrollment. There are between 12 and 25 participants in a class to keep collaborative learning manageable. Online discussions need a critical mass, so smaller is not necessarily better. Subgroups with as few as two or three are useful for the intense exchange required to produce something complex, like a cumulative project. Slightly larger teams of four to five work well for focused dialogue on readings, video clips, simulations, or other shared experiences. In an online environment, these subgroups remain part of the public record so everyone can glean the insights shared in small group exchanges.

High-quality materials. Course designers include the widest feasible range of media and activities to appeal to different styles of learning. In addition to Internet resources, they effectively use books, kits, labs, and other media to supplement online materials. In a science course, for example, students view a visual simulation or use modeling software to understand a concept. Offline, they conduct experiments with simple materials. Web-based graphics or content shed light on other aspects of the subject. Students engage in explorations, surveys, creative works, and self-reflection, as appropriate. Multiple, short assignments using a variety of approaches and media help preserve course flexibility, reinforce key concepts, and nurture different strengths.

Purposeful virtual spaces. In a face-to-face classroom, the structure of conversation is fluid and invisible. We know or learn to do our social chatting before and after class and during breaks. When the instructor asks if people have questions about the assignment, that's when we ask. Online, course designers create explicit structures so the community gets what it needs without interrupting the flow of content-based discussions. Typically included are a "Student Lounge," a "Questions about Assignments," a "Technical Questions," and a "Class Meeting" discussion space for debriefing course experiences.

- **Ongoing assessment.** The idea of using one high-stakes test to measure achievement may work well in a closely monitored classroom. Online, however, assessment is a continuous, ongoing process. Instructors find evidence of achievement in participants' daily contributions to online discussions, and learn each student's unique "voice" and approach to solving problems through their postings. The online version of a literature course, for instance, includes regular small group discussions on assigned readings and essays or longer projects, which undergo a sequence of peer review, revision, and final submission for grading. Instructors hold daily submissions to standards that foster constructive dialogue and learning by communicating clear objectives for project outcomes and specific criteria for postings.

A Framework for Analyzing Online Learning in Post-secondary Education

Leona Rousseau, M.I.D.
Program Leader
Lethbridge Community College
Canada
l.rousseau@lethbridgecollege.ab.ca

Abstract: Can online learning environments facilitate or enhance the cognitive process of learning? Online learning environments are being employed with increasing frequency for post-secondary teaching and learning. Despite existing studies, the ability and capacity of online environments to foster and or enhance the learning process has not been fully ascertained. Factors defining how the cognitive process of learning might be fostered or enhanced remain incomplete as are the specific advantages and disadvantages of online environments as viable new learning environments. If online learning environments cannot be shown to facilitate or enhance the cognitive process of learning, they will be difficult to advocate as new learning environments for higher education. Will online environments fulfill the promise of 'revolutionizing' education, or merely join their predecessors in a cache of teaching and learning strategies. This paper will provide a brief overview of findings from a recent study of online learning in design education and offer a theoretical framework in which to analyze online learning environments in post-secondary programs beyond design.

Introduction

Can online learning environments facilitate or enhance the cognitive process of learning? This paper will provide a brief overview of findings from a recent study of online learning in design education and offer a theoretical framework in which to analyze online learning environments in post-secondary programs beyond design.

Online environments have become a significant influence in our lives with both positive and negative effect. Their presence and persistent use yield both advantages and disadvantages. With escalating use in all business sectors, the complete integration of this technology in post-secondary education has become vital, but how is it best utilized or applied in the academic realm? Post-secondary institutions have embraced and adopted online environments for teaching and learning and will soon be faced with the impact of those swift decisions. Online environments have been touted as having far-reaching benefits to teaching and learning by those with zealous expectations, infectiously spurring further acclaim. In stark contrast, critics argue that while more information may be available there is less knowledge, clearly to the detriment of learners. There is a critical need for what Hlynka calls a "dispassionate middle-ground", a sober look at what online environments realistically have to offer. What might they contribute to learning itself? How can they support the acquisition of knowledge, or can they? How do online environments truly differ from any other media or learning environment? Will online environments fulfill the promise of 'revolutionizing' education, or merely join their predecessors in a cache of teaching and learning strategies.

Online learning environments are being employed with increasing frequency for post-secondary teaching and learning. Academic programs are being pressured by administration, learners and other stakeholders to offer courses and or entire programs online and must decide how to meet these growing demands without compromising quality. Online courses are often implemented without seriously considering or comprehending the impact, the advantages and disadvantages, to learners and the learning process. Despite existing studies, the ability and capacity of online environments to foster and or enhance the learning process has not been fully ascertained. Factors defining how the cognitive process of learning might be fostered or enhanced remain incomplete as are the specific advantages and disadvantages of online environments as viable new learning environments. If online learning environments cannot be shown to facilitate or enhance the cognitive process of learning, they will be difficult to advocate as new learning environments for higher education.

Methodology

An integrative inquiry was recently conducted to determine what, if anything, online environments may uniquely contribute to the cognitive process *of learning to design in post-secondary design* education. Salient knowledge from existing studies was collected, analyzed, and synthesized. Selected data was then organized into a conceptual framework that focused specifically on the cognitive process of knowing or learning and its relevance to the cognitive process of learning to design, allowing new perspectives and insights to be drawn. Lonergan's Method of Human Understanding (his cognitional theory) was employed as the theoretical framework for several reasons that distinguish it from other learning theories and make it a fitting construct for analyzing online learning in post-secondary programs beyond that of design. The method is universal and deals with knowledge acquisition at a fundamental level rather than focusing on specific aspects of learning such as memory, outcomes, observable behaviour or the like. It offers a unique philosophical perspective that takes into account the complex layers of human consciousness, responsibility, ethics, the role of human error in learning and two ways of knowing. The method also provides a means to analyze the impact and potential of online learning environments at each level of the cognitive process, each level of consciousness, in addition to the whole.

Lonergan believed that "all conscious and intentional operations of knowing occur by means of a dynamic interlocking pattern" (Creamer, 1996, p.66) consisting of four primary levels which build on one another: experience, understanding, judgement and decision. The following diagram, derived from Creamer (1996, Table 5.1, p.74), illustrates Lonergan's multi-level Method of Human Understanding.

Level of Human Consciousness		**Questions Evoked at Each Level**
	KNOWING	
Responsible	**DECIDING** Deliberating	(what ought to be done?)
Rational	**JUDGING** Reflecting	(ask is our understanding correct? What is so? True? Valid?)
Intellectual	**UNDERSTANDING** Inquiry Conceiving	**(INSIGHT)** (relationships and meanings…)
Empirical	**EXPERIENCE** Remembering Perceiving Sensing	(imagining, anticipating, feeling…) (seeing, hearing, touching, tasting, smelling)

Figure 1: Levels of Lonergan's Method of Human Understanding

Each level of consciousness cited in Lonergan's method calls on a different and distinct set of human faculties. Ascending vertically through the levels the first, "experience", requires data collection through the five senses and also calls on one's memory, imagination and intuition to inform. The more data or experience that can be observed or gathered, the more complete the level, which improves the potential for success at subsequent levels. The "intellectual" level necessitates investigation and the formulation of ideas and concepts based on the empirical and subconscious data from the previous levels. Lonergan believed it was within this level that "insight" occurred, during which all thoughts from previous levels merged in such a way as to bring about some clarification and understanding of the information or data. It is through "insight" alone that we make the leap from the level of pure data to understanding (Creamer, 1996). Insight is defined as mental acuity, a drawing of relationships between previously disparate bits of data, to suddenly see what previously went unseen. Understanding is not itself knowing but leads to knowing. Knowing requires judgments which Lonergan explains as distinguishing "alchemy" from "chemistry" (Lonergan, 1993, p.147). This elucidation of previous empirical and intellectual levels then leads to the following "rational" questioning of what is known up to that point. The "rational" level requires reflection on data that has been gathered, on thoughts and on insights gained, to determine whether things are what they seem; a double-check as it were, or verification of what is thought to be correct. Then, "judgements" may be made as to the quality, soundness, and accuracy of one's understanding at the current level. The succeeding level of consciousness "responsibility", calls for consideration and review of appropriate and ethical 'actions' that might be taken in light of one's understanding, at which point a final "decision" must be made. The decision is not absolute, but the "most probable" outcome or decision given our understanding of the situation, context, problem or question. Since each level depends on the knowing achieved in the previous level one cannot successfully proceed to the next level until the objective, achieved through self-question and answer, of the preceding level has been satisfactorily met. The cognitive process is dynamic rather than a rigidly defined sequence. The knower or learner oscillates between levels until questions at each level are sufficiently answered. Lonergan believed, as did Plato, Dewey and constructivists today, that the answers to such questions ultimately come from within, from the one seeking knowledge, the knower or learner.

How can aspects of online environments facilitate this process? Can the elements or characteristic aspects of these environments foster knowledge acquisition at each level and knowing as the ultimate outcome?

Findings

In the study conducted, each level of the cognitive process of learning to design (experiencing, understanding, judging, deciding, knowing) was examined in relation to the various elements of online learning environments (such as vast global resources and opportunities for diverse collaborative endeavours) to determine if such elements facilitated or enhanced the cognitive operations at each level and on the whole and to identify the inherent advantages or disadvantages associated with such elements at each level and on the whole. The findings indicated several factors and unique aspects of online learning environments that facilitate/enhance and those that hinder the cognitive process of learning to design at the levels of experience and understanding. For example, while there is an unprecedented volume of accessible information and data from diverse sources online to facilitate the cognitive levels of experience and understanding, these same resources could lead to *mis*understanding and *un*knowing when questionable content is asimilated into the knowing process by the learner.

Results of the study indicate that online learning environments have the potential to facilitate and or enhance the cognitive process of learning to design primarily at the levels of experience and understanding. Due to the predominantly reflective nature of the higher, more complex cognitive levels of judgement and decision, online environments may lack the potential to contribute significantly at these levels of cognition.

Conclusions

Lonergan's Method can be applied as a framework for examining the learning process and product (knowing) in many fields of study. Once the process, the levels of knowledge acquisition in a particular field are understood, elements or aspects of online environments that may facilitate or enhance that process may be determined. While this study focused on design education specifically, the cognitive process of learning remains the same for learners in any post-secondary program and thus the findings may be more generalizable. Regardless of curricula, online learning environments appear to hold the most promise in facilitating or enhancing knowing for the learner at the cognitive levels of experience and understanding with marginal impact expected at the higher cognitive levels of judgement and decision. Online environments could facilitate improvement in the learner's ability to judge and decide if, for example, the online sources accessed, and communication exchanged, elicited deeper reflection or deliberation by the learner. Since each level of Lonergan's Method builds on the preceding level, facilitating or enhancing knowing at the level of experience and understanding can make knowing at subsequent levels of judging and deciding more certain or more 'probable'. In this way, facilitating or enhancing knowing at any level of the cognitive process of learning can to some extent enhance learning as it ultimately contributes to the 'most probable' knowing.

Abstract: The inter-cultural dialog in a contemporary global society is proceeding with amazing speed due to advancement of synchronous and asynchronous telecommunication technologies. Electronic dialog users need to be prepared to use such technologies as e-mail, WWW-based technologies, forums, IRC, etc. Scholars are challenged to develop innovative teaching and learning methods to hold inter-cultural dialog properly and efficiently (basically e-mail and web-form for a Cultural Values survey). Here we present some successful Correspondence, Cultural Value and Communication Projects for language, communication and culture learning run at some Russian and US Universities from 2000 through 2002, based on asynchronous technologies (basically e-mail, and web-form for Cultural Values survey). The results of these projects confirm our pedagogical hypothesis that students from different countries can be themselves language, culture, communication teachers and a source of appropriate knowledge due to asynchronous learning environment design based on e-mail and web technologies.

Introduction

The cross-cultural interaction in a modern global society is proceeding with amazing speed due to advancement of asynchronous and synchronous telecommunication technologies. This means that educational organizations are challenged to teach their students how to use new computer-mediated communication technologies (e-mail, WWW, forums, IRC, etc.) and to research how to develop them properly and efficiently in education. Here we present some successful methodology, which was introduced in joint Correspondence, Cultural Values and Communication joint projects aimed at language, communication and culture learning. The project was carried out by the Institute of Linguistics, Rostov State Pedagogical University; Philology Department of Institute of Management, Business and Law, Russia and English and Communication Departments of Western Kentucky University, USA from 2000 through 2002. The educational activity that we called an educational project helped the students to develop their skills for using telecommunication technologies, which connected them and gave them a more appropriate medium for language and culture learning.

The Theoretical Aspect

The main hypothesis of these projects comes from our understanding that students from different countries can themselves be language, culture, communication teachers and a source of appropriate knowledge. This hypothesis is built on the best known of Lev Vygotsky's social theoretical concept of proximal development zone (ZPD). According to Vygotsky the culture gives students the cognitive tools needed for their development. Foreign students are conduits for the tools of the foreign culture, including language and communication differences. The tools the culture provides students include social context, language and asynchronous telecommunication technologies for interactive connect and information exchange. In turn contemporary telecommunication technologies bring additional methods, tools and criteria for successful learning environment development. Thus we gradually see that the evolution of learning environment is based both upon theoretical and practical grounds.

The first thing that helps educator in this new learning environment is that learners become more active participants. The second is that the learners accept and incorporate previous and current learning practices from different subjects such as language, computing and telecomputing that rely upon emotional and social factors. Thirdly, many successful learning tools were initially not aimed at learning: word processors, spreadsheets, simulations programs, expert systems, email, mailing list and all WWW-based communication tools. In our project virtual learning communities were developed with the goal to activate these tools for new learning environments.

Effective learning is a many-faceted process that benefits from these new tools. Generally, positive characteristics of these application tools for effective learning are follows:

- Stimulating active intellectual involvement on the part of the learner.
- The student, rather than teacher, is in charge of learning activity - students determine when and how they use the computing and telecomputing to support their efforts to present information, collect data, solve problems, collaborate, and persuade others or foreign respondents.
- The learners have a great deal of control of the writing communication via e-mail. Students prefer to use a word processor with grammar and spelling checkers, the thesaurus, vocabularies, various editing aids such as replacements, block moves, coping, citing, etc.
- The correspondence project methods are aimed at accomplishing more creative tasks than traditional methods of teaching language, culture, communication, computing and telecomputing methods.
- These learning media assimilate new genres, fashion in writing (handling, slang, emoticons, abbreviations, signatures, etc), and new network etiquette (netiquette) in order to express meanings.
- Collaboration using learning media promotes mutual tolerance and provides responsibility to make students from both countries conscious of their identity and their responsibility to help one another to learn culture, communication and language as well.

Transcripts were collected from a graduate level virtual conference seminar course taught during summer session, 1998 at Northern Arizona University. Participants were in-service classroom teachers. A kindergarten through high school grade range of classroom assignments was represented by these teachers. Course work included outside class reading assignments of selected current research in the field, a final research paper, and active participation in the on-line discussion forum with focus questions by the instructor. The seminar offered was a Tools for Teachers course designed to promote reflective practice. Seven teachers from four different communities participated in this pilot course during the summer of 1998. Five of the participants were female and two were males. An interactional sociolinguistics (Schiffrin, 1995) approach was used to examine the texts of conversations. This approach draws upon concepts of culture, society, language, and the self. The meaning, structure, and use of language is socially and culturally relative (Gumperz, 1982). Meaning in dialog, like that of conversation, is socially constructed. Data was also examined for evidence of micro displays of sex class linked gender identities; displays that are commonly associated specifically with either gender. An example of this is the use of tag questions. Female participants, much more so than males, tend to use tag questions as a discourse strategy to invite response and inclusion or solidarity within the group. (Tannen, 1994) Simple quantitative analysis was done to determine total lines of text generated by each participant, amount of participation, total sums of questions, statements, as well as number of directed responses sent and received. Patterns of participation were mapped/graphed and correlated to the contexts of interactions. Style, register, and "voice" or tone analysis were also used on the data sets to try to discover the dynamics among the participants.

The Practical Approach

The role of teachers from all classes is to help learners with their communication, culture and language skills. Learners periodically send to their teacher and /or partner teacher a request or a copy of their email to see the communication problem or how they progress and help them if they wish. The pedagogic (cultural and educational) aim is:

- to encourage learners to exchange cultural information,
- to comment / "correct" the language of each other as a form of mutual self-help among students (peer collaboration).

Before the beginning of the Correspondence Project e-mail partners were given some guidelines from their virtual class teachers. For example, the guidelines adapted from the International E-mail Tandem Network (Jane Woodin, 1997 Brammerts, Kleppin, Szymanski 1996-1998, http://www.slf.ruhr-uni-bochum.de/email/help/helpeng01.html#questions). The same approach was used in the Correspondence Project to create learning media between students from Rostov State Pedagogical University and Valenciennes University, France for Russian and French languages study.

Brainstorming was one of the methods we used to prepare ideas and materials for the Correspondence Project. For example, we encouraged our students to brainstorm about their impressions and knowledge of the other country. Then we provided our students with the results of the Internet survey about the traditional impressions, or the list of perceptions, beforehand prepared at partner class or our Cultural Values survey. We asked them to compare results and talk about some topics.

Thus in a class at Rostov State Pedagogical University, the students were asked to brainstorm and express their perceptions of Americans and to freely express what they know about the U.S. Some were repetitions and some were contradictions. We discussed students' own lists for recording and categorizing their impressions. If we had enough answers from a partner class, the most interesting pen pals' responses were shared aloud in class, then discussed. Some cultural information as to why these differences might exist was given. We then divided their responses into positive and negative descriptions. In our current project we listed all terms in order of frequency; therefore, in the last version of the database terms those, those listed first or second were provided by more than one student, perhaps even several students.

In the Cultural Values Project both the Russian and the American students filled out the surveys (hard, soft or Web-based form http://rspu.edu.ru/li/cultural_value/survey_e.html) and exchanged their finding results (personally forwarded to partner or collected as full database of all student responses). In the Cultural Values survey database some values were rated the highest on the Russian responses and certain common or different on the American responses. We came up with a few questions in class for them to ask their pen pals. The teacher helped them with providing some information on the types of things that might be different when comparing the Russian and American cultures. Students discussed results and asked questions based on their partner's most important values and full database results.

In the Communication Project the goal of the assignments was to analyze the mediated (e-mail) communication (computer-mediated communication, CMC) with colleagues from a different culture - American and Russian. To do this, students analyzed their email conversations by applying interpersonal and CMC theories we've discussed in this class. Teachers paired up students for responsibility to maintain e-mail contact between students. Usually at least three to five interchanges occurred between partners. If partner did not respond, teachers tried to assign their student a different partner. Students save copies of all email correspondence (including the copies of messages they sent out). Printouts of these e-mails were included in the students' final paper. For example, American students used any three or more of the communication theories (Norm of Reciprocity, Differences between Men and Women in Communication, Social presence Theory, Media Richness Theory, Hypersonal Interaction Theory). A final paper identifies the theory that they use to analyze the communication with their e-mail partner, give a brief overview of the theory. Students need to determine what communication behavior the theory seeks to explain or describe, use examples taken directly from collected e-mails to either confirm or disprove the specific tenets of each theory.

Usually students conducted each e-mail exchange for one semester. Once each student had a partner, we encouraged them to exchange emails as often as possible. Many of them corresponded more than once a week. We met at a class officially once a week, and teachers mentioned the time and day of our meeting in a mass e-mail to both the American and Russian students, so that they might try to send their replies before the beginning of our class period each week.

We conducted the class in both a formal and informal manner. Therefore, students often felt free to disclose and then revise their initial impressions and correspondence problems. As the students received responses, they would share them with the group. The responses were disclosed usually in the form of reading their partner's original text aloud. We are not sure if they ever revised their initial impressions, since they didn't share many of these original impressions on the lessons.

Conclusion

As a result of these projects, Russian students increased their English vocabulary, positively change their perceptions about Americans and American culture, and began to practice appropriate netiquette even during the course of these one-semester-long projects. The results of this study confirm our hypothesis that students from Russia and the U.S. can themselves be teachers of language, culture, and communication due to an asynchronous learning environment design based on e-mail and web technologies.

Ergonomics of the Study Environment of Online Learners

Carolyn Rude-Parkins
Department of Leadership, Foundations, Human Resource Education
University of Louisville
United States
cparkins@louisville.edu

Abstract: This presentation reports a literature review and a survey of ergonomics of the study environment of online learners. It reviews the parameters of physical ergonomics already established for office-based workers, and applies them to the online learner's reported study environment. Factors of interest include the work station desk, seating, computer monitor, keyboard and mouse, room lighting, and room environment. The online learners were students in virtual university courses offered in Kentucky. They rated conditions of their workstation related to five factors and identified their perception of the importance of each factor.

Introduction

Ergonomics is in the news as the U.S. Department of Labor considers workplace ergonomic rules, recognition of the safety considerations inherent in workstation design. Office ergonomics applies science to workplace design to maximize productivity while reducing operator fatigue and discomfort (Revelle, 2000). Office environments are more likely to be designed for effective, safe, comfortable and efficient work, due in part to office furniture manufacturers' consideration of these factors. But nearly one-third of American households have a home office. Distance learners often spend considerable time at their home workstation, which may not be built around the same ergonomic strategies and principles as the one in their office. University classrooms observe ergonomic design in lighting, chair and table heights. When students participate in their classes in a university setting, there is some control of the ergonomic factors. But distance learners choose and often create their own learning spaces.

According to Alan Hedge, professor of ergonomics at Cornell University, if a person sits at his or her home computer for more than one hour a day, ergonomics need to be a priority (Goff, 1999). "Even worse, the risk of musculoskeletal injury is nine times greater when you spend four hours a day at the computer than it is for a one hour-per-day user." The Bureau of Labor and Statistics finds that musculoskeletal disorders now account for one-third of all occupational illnesses and injuries (Revelle, 2000). These disorders are occurring in the workplace where researchers have been studying the problems, as well as solutions, for many years. Professional groups, unions, employees filing lawsuits and winning judgments, concerned companies with budgets to purchase ergonomically designed furniture and equipment, insurance companies looking to lower their costs, medical practitioners wanting to solve medical problems, etc., are all working together for a safer workplace.

Lone individuals working or studying at home or other "unplanned" locations, do not have all of these groups fighting to protect them. He or she has a paper due for class, and it must be done. Having an ergonomic workstation is the least of their worries. The workstation may be a card table or a kitchen table. The seat may be a stool, sofa, or kitchen chair. Lighting will be whatever is available for normal household use.

Literature Review

Researchers have found that when a learning environment is well designed, a high caliber of learning will occur (Knirk, 1987; Woodson, 1992). Additionally, "the physical environment impacts on learners not only physiologically, but also emotionally and psychologically" (Knirk, 1992). Inappropriate conditions take a physical and mental toll in terms of visual stress, musculoskeletal stress and psychological stress (Yeaman, 1986).

An issue raised in the literature is whether or not students are being taught about ergonomics, and potential health risks associated with computer use. Yeaman (1986) recommends a preventive ergonomics approach which would teach students what the potential problems might be. Rasicot (2000) opines that educators are "training" the workforce of the future, but aren't teaching, let alone demonstrating, how to prevent these ever increasing problems. Yoder (1993) questions whether or not we've forgotten ergonomics, and are now indirectly teaching students how to get carpel tunnel syndrome. Adults over 30 who learned keyboarding using a typewriter (pre-PC days) learned posture, machine alignment, lighting, chair and table height considerations, as basics taught in every class. Schools that do not teach or practice ergonomics in the classroom could be putting students at risk for future injuries" (Rasicot, 2000, p.24).

This literature review offers a brief look at specific components that are the focus of this study: workstation seating and desk, computer keyboard, monitor and mouse, room lighting and room environment

The first element is the workstation. Whether one is creating a workstation for his or herself, or creating a computer lab at a university, adjustability is the key to setting up ergonomically correct workstations (Rasicot, 2000). Getting the most accurate adjustment for the individual user at the time of use is the prime objective of ergonomics. Comparatively little research has been done on the home office, while countless studies have been conducted on the workplace ergonomics of the workstation (Robertson, 1992; Wright and Friend, 1992; Yeaman, 1986).

Another issue distance students confront is the keyboard type and placement. "One of the worst problems is badly placed keyboards. Arms should be level. Wrists should be flat, much like a piano player. Wrists should not rest on the computer keyboard or table when typing." (Yoder, 1993, p. 30).

Seating is an absolutely essential element to a well-designed workstation. Not only does it immediately influence the user's comfort, it also affects the way one interacts with the rest of the workstation (Badolato, 1995; ANSI/HFS, 1988). Seating has been identified as the most frequent source of health-related symptoms by office workers, regardless of whether or not their job functions entailed the use of VDTs

The Video Display Terminal (VDT) is another issue in home office ergonomics. Badolato (1995) observed that a typical VDT user views not only the VDT screen but also the printed materials used in the task being performed. Therefore, in planning a workstation, one needs to consider both. As for the visual display itself, one needs to consider the following five elements: the size of the display, the height of the display, the distance between the display and the viewer, the viewer's angle of observation, and the viewer's need for sharp detail (Leed and Leed, 1987, p. 234).

Issues of lighting for computer workstations are complex. They must illuminate the work surface where documents might be, but they must also be positioned so as not to create glare on the computer monitor. "Lighting is but one aspect of the luminous environment of any workspace, as part of the collective balance of general illuminance levels, window light control, and surface reflectance and contrast. All of these aspects must work together to provide a visual environment that facilitates learning and productivity without being distracting, tiring, unpleasant, or otherwise inadequate to the task" (Badolato, 1995, p. 39). "The varying recommendations for lighting VDT work spaces are in part due to the need to maintain balance between the lower light level requirements for viewing the VDT, and the higher requirements of hardcopy tasks" (Badolato, 1995, p. 40).

Distance Learners may use laptop computers for their work, however the state of Minnesota does not recommend laptops as primary computers. Cornell University's Ergonomics Web (CUergo, 2001) site offers tips for using a laptop computer. It suggests that for laptop posture, occasional users are better off sacrificing neck posture rather than wrist posture. Full-time users should attempt to set up their laptop as close to a desktop configuration as possible. Mobil professionals who frequently transport a computer need to consider not only the size and weight of the computer, but also the accessories that go with it. If the total system weighs 10 lbs or more, they should consider a carry-on type bag that can be pulled along.

When deciding what to put into a home office, remember that something is ergonomic if it fits you. "People have to remember that if they are going to spend $1500 on a computer, then they need to spend $500 on a workstation, or else it is like buying a nice suit with no tie or shoes" (Goff, 1999). In addition, it is essential to examine the entire work environment to determine all possible causes of discomfort. In other words, it is unlikely that changing only one workplace element, such as the keyboard, will eliminate all discomfort and disorders. It is more important to pay attention to the basics – including good lighting and a desk that isn't facing the window to avoid glare – than investing in gadgets. "In most homes, I suspect that does not happen. But it is absolutely important. The beauty of working at home is you have control over these things (Goff, 1999).

The Survey

The survey instrument used in this study is based upon the literature review and is an adaptation of Badolato's (1995) survey. It contains 65 questions and is web based, allowing electronic data collection. The sections include questions about the study environment's seating, desk, monitor and mouse, room lighting, and room environment. The subjects are students in online university courses offered in Kentucky in fall 2002. Demographic data include questions on the student's physical size, gender, special needs, amount of daily and weekly use of a computer, location of their work area, characteristics of equipment used and type of connection. Data collection is under way as this paper is submitted.

Educational Technology in the Classroom: Emphasizing Process Before Training

Until teachers understand how, when, why, where to use technology as a tool for learning, technology integration in their classrooms will not take place. Technology integration has not happened by placing a computer in every classroom, by training teachers in a one-day in-service to use PowerPoint, or by "grading" teachers on their use of technology on teacher assessment instruments. The issue is, then, what can be done to help teachers understand and use technology as an integrated tool for student learning?

Classroom teachers are faced with a major dilemma. They know that their students, now called the "net generation" (Wright, 2001), have technology skills that may exceed their own. In fact this techno-generation's skills in technology use is expanding at exponential rates. Parents of this generation, expect their children to be technologically challenged to increase skills, and that their children's education be fun, interesting, and entertaining. Moreover, parents expect their children's education to be "customized, flexible, and immediate" (Hay, 2000). Faced with students whose expertise is greater than the teachers, parents who expect a tailored education, and administrators who evaluate teachers on their use of technology in the classroom. Add to this equation the public's belief and the media's reinforcement of that belief that teachers are not adequately educating children in the basic areas of reading, writing, and arithmetic. Is it any wonder that teachers are confused, frustrated, and at times resistant to the use of technology?

The status quo is definitely not working. Computers sit in the back of the classroom used only by a few students as a reward for finishing their work or by the teacher to do administrative work while children are in other classrooms. In-service information is carefully filed away, and teacher unions are fighting the technology requirement on assessment instruments. What is needed is a change in focus. Technology should not, and was not intended to be, the focus in classroom instruction. Teachers do not (or should not) teach technology—they should teach their content. When teachers say, "I am teaching computer today." We should be asking why.

Teachers need to be reassured that the primary focus of their teaching is on the content of their courses. Technology is used as a tool for learning. Once teachers understand that their basic responsibilities have remained intact, in-service training and practice of technology integration can occur.

The first step in technology integration at Robert Morris University (RMU) is to assure teachers that their content is the focus. The RMU program starts in traditional ways. We teach our pre-service teachers and train our faculty and pubic school faculty to create content rich lesson plans. Our preferred design is a modification of the Madeline Hunter design. We then ask teachers to evaluate their plan using the ASSURE model to aid in technology integration as an instructional and learning tool.

In structuring our program, the questions for us became, how do teachers design classroom instruction in ways that infuse instructional technologies for a positive learning intervention and how can we teach this to our preservice teachers? The answer lies in teaching careful planning. Lesson planning can follow a design format such as *ASSURE* (Heinich et al, 2000). This design formula considers such pedagogical factors as: anticipate audience (A), state objectives (S), select technology (S), utilize technology (U), require learner participation (R), and evaluate lesson (E). Certainly not unique, this formula follows a general blueprint for lesson plan design with one exception—integration of technology.

Using this model, teachers anticipate the type of learners in their classrooms. To do this, we ask that teachers survey their students using one of several learning style inventories as to the type of learning style students feel most comfortable. Teachers are often surprised that many of their students are not visual or auditory learners. They often discover that while their students have a preferred learning style, students are comfortable with a mixture of styles. We also suggest that teachers survey their students before introducing a new unit or concept. There are several ways in which we suggest that teachers complete this step, but the point is that teachers need to know what their students know before teaching. Although many teachers understand the importance of knowing what their students know before teaching, it is even more critical when using technology.

According to a 1999 survey, 71 % of "U.S. households with children ages 8-17 have computers, and 67% of those computers are connected to the Internet" (Annenberg Public Policy Center, 2000). What this means to public school teachers is that many of their students technologically aware of the ways in which the computer and Internet can be used as a learning tool, many are comfortable with using these technologies without teacher instruction. Even more importantly, Tapscott (1999) argues, that because children come to school with these skills, "liner learning [must] give way to hypermedia-based learning, instruction becomes construction and discovery, teacher-centered instruction cedes to learner-centered instruction."

The next step in the ASSURE model is to state behavioral objectives. Good teachers have good behavioral objectives for their lessons; however, they do not always state these objectives for their students. ASSURE emphasizes the need to clearly state the objectives in ways that the students understand what they are to do. At RMU, we teach the writing of behavior objectives using Bloom's taxonomy. This ensures that teachers and students know what the expectations of the lesson and that students are clearly engaged in active learning. In the ASSURE model, the objectives for the class will be written from a pedagogical point of view based on the specific course outline.

Technology planning then occurs in the execution the objectives of the lesson—the next two steps of the ASSURE model focuses on the when, where, and how to use the technology. We ask that teachers inventory the types of technologies available to them (both hardware and software). The inventory needs to be updated frequently, and it ensures that teachers are aware of new purchases or equipment failures. After the inventory, teachers select the technology they feel will be facilitate learning. The technology is selected to better facilitate the objectives of the lesson and the type of learners in the class. Next, the teacher must utilize the technologies in a professional manner. A fluid delivery helps to ensure learning; therefore, we stress the need to practice delivery with the technology. During this step, teachers can evaluate their use of technology. We ask teachers to answer the following question, "Where was the focus of the lesson—on the content or on the technology?" Unless teachers feel as comfortable with using technology as they do the overhead, for example, the technology becomes an "add-on" component of the lesson instead of an integrated part. Essentially, this design formula promotes a positive intervention of technology into teaching.

Next, the ASSURE model requires that students are actively participating in learning. The most often type of technology that we observe in classrooms is teachers using

PowerPoint presentations. During these presentations, the lights are down, students are staring ahead or are given instructions to "take notes," and teachers read the text on the slides. In this scenario students are not actively engaged in learning. They are merely observers of learning. We suggest that teachers allow students to participate by creating some of the slides, using graphic organizers (either on line or hard copies) while information is being disseminated, and that students are required to "research" information via the Internet to add to the learning. Even very young students can and do help to create information that can be uploaded to the class web page, create new letters using publishing software to send to parents, print pictures and other information from Internet sources, use electronic libraries to find articles, and use other software to help their peers gain a better and more complete understanding of concepts and ideas. We suggest that teachers brainstorm various ways that students can become more involved in their learning. We realize that student involvement may require the teacher to reorganize the physical layout of the classroom, redirect time on task, and redo lesson plans. We know, however, that when students are actively participating in their learning and have ownership of their learning, they will take more responsibility for their learning.

Finally, the ASSURE model requires that teachers evaluate the lesson and the student learning. Teachers need to carefully reflect on the positive and negative aspects of the lesson. The model, however, also requires that students evaluate their learning. This is important—and perhaps a little different—in that students are not often asked about what they learned and if the way in which information was delivered was beneficial to them. By knowing what is working and what is not, teachers can better plan for the next lesson.

Using technology as a positive intervention implies a conceptual understanding of technology as more than a motivational tool or a substitute for more traditional types of instructional methods or pedagogy. It means that technology must not be thought of as a reward for students who have finished their schoolwork. Understanding technology as a positive intervention means that teachers do not use technology for drill and skill programs for remedial students and a reward or enrichment activity for their gifted and talented students; instead, technology must be thought as a way to help all children, whatever their ability level, use technology in the same ways they use and are given access to other intervention techniques and methods.

Newman (1990) examined this issue of intervention and formulated the framework for six critical questions. These include the following:

1 What is the pedagogical goal of the lesson, and what pedagogical theory does it satisfy?
2 What is the instructional intervention that has the potential to achieve the identified pedagogical goal?
3 As the intervention is implemented, what factors enhance or inhibit its effectiveness in achieving the pedagogical goal?
4 How can intervention and its implementation be modified to achieve more effectively the pedagogical goal?
5 How has the instructional environment changed as a result of the intervention?
6 What unanticipated positive or negative effects does the intervention produce? (Reinkins & Watkins, 2000).

The ASSURE model helps to answer the above questions; it also helps teachers understand the importance of using technology as an integrated learning tool.

A custom fit

The general trend in the use of technology in k-12 schools has been to "streamline" the process through an approach that basically requires familiarity if not expertise using specific software in prescribed ways (usually project-based). While this is not an "incorrect" approach, my own observations and research have demonstrated that it favors students who already have both computer and academic skills and places inexperienced and/or under-achieving students at a disadvantage. This in spite of the widely held belief idea that technology in schools lowers the discrepancy between different schools and districts. In other words, the "digital divide" extends beyond technology access to a question of "appropriate" technology access.

Self-paced and self-evaluative instruction that adapts to the skill level and time required of individual users has been developed (and introduced) in recognition to this multiple user/multiple needs. This has proven effective, but leaves out some crucial scaffolding required by the second "needier' student group.

My hypothesis is that more academically experienced and successful students already have a variety of schema and learning strategies as well as hands-on computer experience that they bring to a new learning situation which employs [computer] technology. A model for teaching with technology based on such students almost guarantees further alienation and sense of disempowerment on the part of the students in the second group. Merely providing powerful tools does little to encourage an interest in learning in these individuals.

I have sequenced the use of computer technology by the students through four distinct steps. In the first, content is provided by models/examples/simulations. Students respond to questions using self-paced and looped learning software. (i.e. incorrect responses allow for another viewing of the content area.) This is much like the existing self-paced and self-evaluative instruction mentioned earlier.

In the second step students and the teacher/instructor look at the underlying structure and design of provided examples. They use concept and idea mapping software to create graphic models of these efforts, and then use the same software to plan and outline a project of their own.

The third step has the students using software of various sorts (word processing, graphics, presentation, etc.)) to actually design and create projects that are consistent with their outlines.

The final stage has students present the projects to the class, providing an overview, answering questions, and summarizing their efforts.

This approach has proven itself to be effective in a variety of ways. Students remember the material better, can discuss and present their point of view more persuasively, and -in general - are more engaged, which - given the nature of the audience - is probably the most important thing. The reasons for this are fairly straightforward:

- Having little experience with either appropriate models or responses, students cannot be assumed to know how to properly use software, regardless of its level of complexity. Offering such models as well as a means to analyze and deconstruct them is crucial.
- Applying this new analytical knowledge to thinking about and creating a framework for a new project allows - in fact requires- higher thinking skills.
- Making use of production tools to give actual form and shape to the project not only reinforces the relationship between plan and content but emphasizes the process.
- Presenting the material to an audience forces a critical distance and an analysis to allow a view of the initial concept, the actual plan/structure, and the finished product in addition to the development of communication skills often sorely required by this audience.

Much of this is a staple in the day-to-day things that a teacher will do in a classroom, but it has not yet really been applied to the use of technology in the classroom. At this point I don't believe that specific hardware or software is crucial to the educational use of technology or that it will make a significant difference to the learning process of a student unless it is specific to the context and learning needs of that individual.

I have been working with a participating teacher in a continuation high school in San Bernardino, California. All of the students are individuals who have been transferred to this school because of academic and behavioral problems at their previous schools. Such schools are the last stop in a "open" system; after this individuals will go to the "Juvenile Hall" schools which are the current version of "reform schools" ; in both cases generally regarded as the introduction to the prison system. In this specific instance, we have taken a collection of recycled computers (both Mac and PC) and set up a computer lab environment that allows students access to the web as well as a variety of programs, but that is hardly "high-tech". We have introduced a sequenced program in economics, history, and geography that is individuated and that allows students to deal with the content in the ways outlined above. Our results have been remarkable on all levels, from attendance (traditionally a problem with such students) to test scores to more qualitative indicators (types of projects, student interaction, etc.)

I believe this research suggests an additional approach or perspective to technology instruction within teacher training. I still need to conclude my study, and I would like to follow it up with further research (different content, applications, broader samples, etc.) as well as extend the study to other Colleges of Education.

The Internet in Education: Two Different Examples

Nicoletta Sala
Academy of Architecture - University of Italian Switzerland
CH 6850 Mendrisio – Switzerland –
nsala @ arch.unisi.ch

Abstract The Internet is a good resource in teaching and learning activities. The aim of this paper is to present two different experiences which involve the Internet in educational paths in high school and university. In our first experience, named Web Learning Environment (WLE), we have evaluated the use of the WEB and its resources to develop a learning environment. We have applied our approach in a classroom (sixteen students, aged 16-17) of a high school in Italy. The project has been divided in six different phases: the knowledge of the Internet, the research in the Internet, the access to the FTP, the didactics with the Internet, the communication using the "Net", and the creation of a cooperative hypertext. Second experience, named "Cybermath", is an attempt to build some hypermedia modules to introduce the fundamental of Mathematics in a undergraduate course at the Academy of Architecture of Mendrisio (University of Italian Switzerland), Switzerland.

Introduction

The Internet and computer systems have been testified to have significant impact on learning and teaching Using the new media and the Internet in the learning process we have observed that the role of the classroom teacher is evolving from that of a giver of information to that of a facilitator of student learning (Sala, 1999; Sala, 2001). The aim of this paper is to present two our different experiences which involve a high school and university. The first project, named Web Learning Environment (WLE), represents an attempt to stimulate the active use of the Internet (and its resources) in the educational process. For this reason it has been divided in six different phases: the knowledge of the Internet (directly in the Web), the research of some educational information in the Internet, the access to the FTP (e.g. to download some interesting software tools to introduce in the educational process), the didactics with the Internet (using educational hypermedia online), the creation of a cooperative hypertext, and the communication using the Internet. The aim of our second project, named "Cybermath", was to create a remedial course of Mathematics to help the heterogeneous students that attend the Academy of Architecture of Mendrisio (Switzerland).

First Experience: The Internet To Create A Learning Environment In A High School

Innovative use of technology combines telecommunications (e-mail, online resources), multimedia authoring (home page editors), user-friendly convenient applications software are modifying respectively the role of the teachers and of the students in the didactic environment. The role of the classroom teacher is evolving from that of a giver of information to that of a facilitator of student learning. The role of the students is more active than the last years. Our first educational project is an attempt to build an active learning environment using the Internet. It has been divided in six phases: the knowledge of the Internet, the research in the Internet, the access to the FTP, the didactics with the Internet, the creation of a cooperative hypertext, and the communication using the "Net". In the first phase the students, organised in eight groups each composed by two persons, have learnt the Internet directly in the Web using some special interactive lessons, developed by the "Polo Didattico e di Ricerca di Crema" Italy. These lessons are available at the Internet address: http://weblab. crema.unimi.it/ internetcourse/. Using these interactive lessons the students have learnt: the story of the Internet, the correct navigation in the Web, the recognition of the different types of hyperlinks (e.g. hot words, icons, buttons, and images), the netiquette, and the basis of the telecommunications (computer networks, protocols). In the final part of this phase we have proposed to the students a test to evaluate the knowledge on the subjects explain in the hypertext lessons. In the he second phase our students have learnt to use the search engines (e.g. Altavista, Yahoo, Google, Vivisimo), comparing their performances using the same keywords. They have also discussed these results using an information technology point of view. In the third phase the students have analysed the capability to download, to install and to use some shareware and freeware software (on mathematics, geometry, Italian literature, information technology) in their educational process. In the four phase the students have used some educational Internet sites dedicated to the Italian literature, to the physics, and to the mathematics. The students have improved their composition technique, after the exercises proposed on these Internet sites. In the fifth stage the students have created a cooperative hypertext (using HTML) dedicated to Bonaventura Cavalieri (1598 - 1647) (an Italian mathematician) for an International Conference of Mathematics. In course of execution the phases have been: the bibliographical research of information (using some traditional textbooks and the Internet); the choice of information to put in the hypertext; the hypertext's story board; the realisation of the user interface; the encoding of information in hypertextual form; the control of hypertext (links, hot words, etc.). Sixteen students, organised in eight work groups, have developed the following parts: "Cavalieri's biography"; "Cavalieri: the religious figure", "Cavalieri's scientific production", "Cavalieri and the town of Verbania", "Bibliography", and "Other sites on Cavalieri" (with some links to other Internet sites). The students put a particular care to make "friendly" the user interface for easy navigation, and to avoid the "Lost in hyperspace" problem (Conklin, 1987; Calvi,1997). This hypertext, available at the Internet address: http://www.verbania.alpcom.it/scuole/cavalieri/cav0e.htm, has been written in two languages: Italian and English, and it has been organized in a hierarchical structure, because to avoid some of the navigational issues associated with hypertext (Girill & Luk, 1992; Lin & Davidson-Shivers, 1996; Last et al, 2001; Stanton et al., 2001). This phase is an example of "Learning by Doing" environment because the students have also learnt the history of mathematics during the hypertext development. This is also an example of cooperative learning (e.g. to build the knowledge of the use of the software and hardware tools involved in the hypertext development). After this phase we have controlled the students' learning rate using some tests. The sixth phase has been dedicated to the asynchronous communication with other European schools using the e-mail. In a particular case a disabled student of our classroom has researched some Italian and Swiss "cyber-friends". Internet became for him a new way to overcome his handicap and his isolation. In this case, the absence of face-to-face cues and prior personal knowledge of the other students have helped the disabled student to overcame his inhibition.

Second Experience: The Internet To Create A Learning Environment In University

Second experience involves the use of the Internet to build a hypermedia course of Mathematics (Sala, 2001). This hypermedia course, named "Cybermath", is necessary because the students that attend the Academy Architecture of Mendrisio (University of Italian Switzerland) come from different countries and different kinds of high schools, for this reason the project "Cybermath" intends to develop a propaedeutic course of Mathematics to introduce some particular subjects. The aim of the project is to help the students to overcome the strong dislike for the mathematical subjects using a medium, the computer, which has a good communicative impact. Inside this project different media are involved, but their use is calibrated to avoid the cognitive overloaded; for example: animation techniques (e. g., the generation of a cosine function a or conic); digitised television camera images to illustrate some architectural application of mathematical concepts (e.g., the golden section or the symmetry); audio supports to stress some topics in a lesson where it is not possible to use a written description; Virtual Reality environment (e.g. to manipulate some particular geometrical objects).The project intends to develop a distance learning model:

- to introduce the fundamental of Mathematics;
- to permit to the students to overcome the problems of the different background before the beginning of the academic year;
- to help the students to reach a good grounding in Mathematics.

We have established the following didactic objectives:

- to know and to apply the fundamental of the Algebra and Analytical Geometry,
- to solve some typical problem of the Analytical Geometry,
- to know and to apply the fundamental of the Trigonometry,
- to know and to apply the fundamental of the Mathematical Analysis,
- to know the interconnections between the Mathematics and the real world (e.g., the mathematical applications in architecture, in economics, in arts, and life science),
- to prepare the students to use the new media inside a continuos training.

Figure 1 shows our Distance Learning Environment.

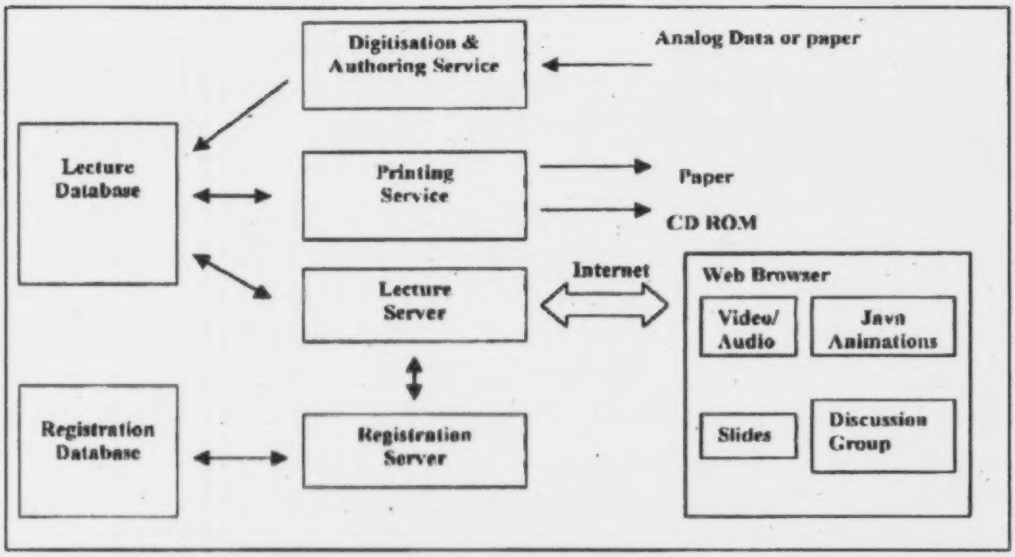

Figure 1 Cybermath's Distance Learning Environment.

"Cybermath" learning environment provides the user registration; the hypermedia lessons; the course materials; the tests online; some active links to other Internet sites dedicated to the mathematics.

The modular structure of this project will permit the addition of the other modules that will render the course flexible for all faculties where the Mathematics is present. This hypermedia course is structured on a set of lessons (modules), in three languages: Italian, English, and German. In each module, organized like a hierarchical hypertext, the graphics interface is "user friendly" for an easy navigation (to avoid the Conklin's problem "lost in hyperspace") (Conklin, 1987). The learners can use "Cybermeth" in two different ways:

- the asynchronous use of the hypermedia online modules (e.g., students study at home using different ways to communicate with the tutors: e-mail, Forum of discussion and Video Conference);
- the synchronous use of the modules, in university, with the presence of the tutors.

In this way, the students can adapt the learning rate to their time availability and cultural background. They can study the fundamental of Mathematics using the Internet as a medium to receive the information, and then self-verify their knowledge level by solving practical exercises and answering a series of questions. Each lecture includes several tests to control the level of the acquired knowledge on the educational objectives and lesson subjects. Examinations include: simple questions or problems, and multiple choice tests. Other important educational objective is to train the students to integrate the hypermedia solutions in their learning processes and in their vocational training. This hypermedia course is organised in six modules using a hierarchical hypertext. In fact, recent researches showed that a more tree-like or hierarchical text structure limits navigational difficulties as compared to a purely heterarchical structure (Girill & Luk, 1992; Stanton et al., 1992; Lin & Davidson-Shivers, 1996; Billingsly, 1982). The hypermedia modules have been written using the Dynamic Hypertext Markup Language (DHTML) with the aid of Java Applet and Java-Script procedures to introduce multimedia codes. Virtual objects, e.g. virtual polyhedra, created using Virtual Reality Language Modelling (VRLM) are also used to help the leaning impact.

Conclusions

Our projects are two different attempts which propose an active use of the Internet and the World Wide Web inside the teaching process in agreement with other researches (Putri Ratna et al. 2001, Maraschi et al., 2001, Choi et al., 2001). The "Net" and the multimedia technologies offer significant benefits in educational process, and they show that there are clear educational advantages to be derived from cooperative student activities. Our projects present a modification of the role of the teacher. Before information technology revolution, the teacher was only a giver of information now he is a facilitator of student learning. This approach is in agreement with Papert's point of view: "Better learning will not come from finding better ways for the teacher to instruct but from giving the learner better opportunities to construct" (Papert, 1990, p. 3). The typical student of the new millennium will be academically independent and will study using distance learning modules. He will be self-motivated with an inquiring nature. This student will be able to articulate questions and will be better able to discuss academic subject matter than the students educated in today's traditional classroom environment (Ben-Jacob et al., 2000). The benefits to develop an educational environment using the "Net" are learning without any restrictions as time or space; courses based on modules with flexible time schemes; great responsibility taken by students in the learning process, and active role of the students in their learning environment.

Abstract: This work presents **Mistral** an intelligent platform for distance education that fully automates the process of creating and maintaining adaptative courses on World Wide Web (WWW).

The first section of the paper analyzes the state of the art in the area of authoring tools for intelligent tutoring systems and adaptive educational systems, folowed by a description of the authoring and deployment processes. The next section centers on the course creation process. The paper finishes with one empirical results taken from one real authoring experiences and the conclusions derived from them.

INTRODUCTION

Between 1970 and 1990, computer-assisted teaching was strongly influenced by the incorporation of Artificial Intelligence techniques into the ways computer systems and new teaching strategies were developed. Seymour Papert and Marvin Minsky, to take just two examples, regarded computer science not only as an explanatory instrument of the way learning and thought function, but also as an instrument for change which could alter and possibly even improve the way people learn and think [Papert, 1981]. A concrete example of this can be seen in the work of PEG (the PROLOG Education Group) in the University of Exeter (in Great Britain). This group works on the design and application of "open education" programs which facilitate students' work in the organization of and access to important knowledge through historical simulations, problem-solving adventure simulations, and so on.

Looking elsewhere, we find two main types of application: *intelligent tutoring systems* (ITS) and *interactive learning systems*. "Microworlds" contextualised in *environments of interactive development* are the most developed of this type of application.

Intelligent tutoring systems generally have well-defined and commonly accepted learning objectives like factual knowledge and procedural abilities – this being the result of an objective perspective of knowledge – which can be measured through standardized tests. The developers of these systems have used traditional learning, teaching and evaluation methods to try to show that they have significantly improved the speed and quality of students' learning. And, to a certain extent, they have successfully achieved their aim.

Although the full bibliography is incredibly large, it is possible to cite several books, articles and congresses which have compiled the work done in the last few years: [Wenger,87], [Clancey,87], [Self,88], [ITS,88], [BBS,89], [ElCo,90], [Fra Ga,90], [Birn,91a], [Good,91], [FaPso,92], [Costa,92], [ITS,92], [PoRi,92], [ReShu,92], [LaDe,93], [GreMc,94], [Salcedo,99], [SaFa,96], [SaFa,00], [SchaCle,95], [ITS,96], [Regian,97], [ITS,98], [ITS,00], [KeFoFe,01] and [ITS,02].

During the last decade, ITSs and Adaptive Hypermedia Systems (AHS) have overcome their laboratory prototype status and have begun to be installed in classrooms and in workplaces, showing themselves to be very effective [Murray, 1999]. Despite the fact that these systems are every day more widespread and efficient, they are still difficult and expensive to build, a factor impeding their wider use. In order to foster the creation and use of these systems, the objective has been established to build "authoring tools" in order to facilitate the construction process for people without past experience of Artificial Intelligence. The study of these tools has arisen practically at the same time as the ITSs themselves, and different prototypes have already been constructed. In his work *Authoring Intelligent Tutoring Systems: An Analysis of the State of the Art* [Murray, 1999], Tom Murray describes each prototype's particular characteristics as concerns the creation of the teaching-learning system and the tutoring system which is generated.

Moreover, the rise of the Internet over the past few years has led to projects which relate to its use for distance education. Distance education systems on the World Wide Web, based on the use of AHS and ITS, have become especially important. The same can of course be said of systems, or platforms, that include "authoring tools", which have meant that these systems can actually be developed. Several of these systems are described below:

- **TANGOW** (Task-based Adaptive learNer Guidance On the Web). This platform is designed to develop courses over the Internet [Carro, 2001] which can adapt to students, taking into account their personal characteristics (age, language, etc) as well as their achievements during the learning process.
- **APHID** [Kettel, Thomson & Greer, 2000] is a prototype which semi-automatically generates personalized hypermedia applications based on a group of hypermedia elements, a domain model and a learner model.
- The **AHA (Adaptive Hypermedia Architecture)** system [Bra & Calvi, 1998] facilitates the creation of adaptive courses for the World Wide Web. The AHA system is based entirely on the Web, in so much as it only uses standard languages and tools. In order to develop an adaptive course, one only needs to create a group of HTML pages and add comments to them, including the conditional instructions which are evaluated, in order to decide which contents will be shown to users and which will not.
- **Arthur** [Gilbert & Han, 1999] compiles the different teaching styles of different instructors who teach the same contents and makes them available to each student.

The system proposed by this article serves a similar purpose: *MISTRAL* is an aid for developing adaptive and accessible courses over the Internet. Its usefulness resides in how it helps teachers, who are not experts in computing, to construct teaching-learning systems in the specific fields in which they *are* experts. It facilitates personalized teaching in which courses can adapt to students' learning strategies and requirements.

2. MISTRAL. General Description

The functions of *MISTRAL* can be summarized as follows:

- It makes possible the planning and administration of different courses for multi-users.
- It facilitates the acquisition of knowledge.
- It builds the concrete structure of the course (AHS/ITS) from the specifications of given contents and activities.
- It is based on the evaluation strategy of "Portfolios". It generates, on the server, a folder structure for each course and student where the latter can deposit his/her activities so that the teacher can evaluate him/her later using the portfolio technique.
- It incorporates knowledge in order to detect and diagnose the level of learning achieved in the unit and the sequence of activities necessary to support the unit.

- It automatically generates a personalized Virtual Classroom, with discussion groups in which students with different learning styles participate. In order to strengthen their different styles, class-members contact each other by electronic mail. A participatory follow-up system notifies students (again by e-mail) of low participation in certain activities.
- It builds the course, selecting or generating regulations and whatever else is necessitated by the knowledge specified (which can be modified or updated).

3. The Process of Constructing a Course using *MISTRAL*

This process has two phases:

- *Phase 1: entering the domain*. The main purpose of this phase is to structure the knowledge that the system acquires into objectives from which derive the contents as well as the different activities that the teacher or administrator deposits on the server.
- *Phase 2: incorporating learning strategies and evaluation*. The main purpose of this phase is to incorporate the sequence of activities which corresponds to a concrete style and form of evaluation.

4. Example

Thanks to the *MISTRAL* platform, various courses and adaptive Websites have already been developed. Evaluations have proved the effectiveness of *MISTRAL* as a system for teaching and administering distance courses.

The first course developed with *MISTRAL*, whose main objective was to exemplify how the system works, was related to "Analysis and Design Oriented to Objects" for third-year IT Engineering. The course provides proof of the different possibilities of the platform's adaptability:

- The structure of the course adapted itself to the students' personal characteristics as well as to their pre-knowledge of programming languages and modeling tools. The designer (a teacher) decided to incorporate the possibility of choosing the programming language to be used during the course (C++, Pascal Object, Visual Basic, etc) or starting with a review or in-depth study of a language and choosing the modeling tool (Rational Rose, Microsoft Visual Modeler, GDPro, etc) which allowed him to adapt activities and the sequence of the contents.
- The structure of the course could be adapted to suit each student's learning style. The system measured each student's style and later adapted the most suitable strategy to his/her characteristics.
- After the student developed the sequence of activities most appropriate to his/her style as suggested by the system, the structure of the course was adapted to the learning he/she had accomplished. If the student had not accomplished the minimum grade during the evaluation, the system proposed a series of complementary activities (different from the previous ones) which allowed the student to improve his/her learning.
- The activities suggested by the teacher were very diverse, saving him a considerable amount of work, thereby creating the possibility of using material which already existed on the Internet.
- The private discussion group brought together students with different learning styles so that these different styles could be encouraged.
- The possibility of depositing different types of work on the server (portfolio technique) allowed both the student and the teacher to revise what they had accomplished.

Conclusions

In this article, I have presented a tool which will help to create and administer adaptive distance courses over the Internet. With *MISTRAL*, course structures and contents are managed independently, thus facilitating the process of adapting to each student.

Once more courses have been successfully developed with this educational distance platform, our next goal is to validate *MISTRAL* tools in terms of the actual facilities that *MISTRAL* provides for constructing and administering new distance courses. Our hope is that *MISTRAL* will be validated and put into practice as a result of the success of these courses' learning-teaching processes.

Integration of Cognitive Theories into the Instructional Design of Educational Technologies

The focus of this discussion is the incorporation of cognitive theories in the instructional design of educational technologies. The specific topics covered include simulations for business games and medical studies as well as how cognitive theories can be applied to distance learning courses taught using a course management system such as Blackboard. It is critical to apply theories of cognition to how individuals learn in these environments. Such environments have the possibility of providing a dynamic experience for the user and provide a vehicle for life-long learning.

The recommendations provided in this paper focus on how instructional technology should be designed using theories of cognition. Issues of how content should be presented include context, opportunity for practice and elaboration, incorporation of visual aides, and the hierarchical organization of material. In addition, visual perception and recognition are considered in the development of realistic simulations.

1. Recommendation: The context in which information is presented should enable students to process the information at a deeper level.

Validity of Recommendation:

The level of processing determines the amount of information that will be remembered. Better learning will result if information is presented in a context that allows learners to participate in elaborative processing. Anderson and Bower (1972, as cited in Anderson, 2000) had subjects try to remember simple sentences. In one condition subjects just studied the sentences and in the second condition subjects were asked to generate an their own elaborations. Subjects who created their own elaborations were better at recall. It is speculated that the advantage was caused by the redundancy created by the elaboration.

Elaborations created by either the teacher or student are successful as long as the information to be learned is enhanced by this process. Stein and Bransford (1979, as cited in Anderson, 2000) created groups that required students to remember a set of simple sentences. In one group subjects were required to generate their own elaborations which helped in recall. Subjects in the experimenter-generated elaborations had better recall because the elaborations were carefully constructed to enable information retention.

Context can greatly influence memory by affecting what is encoded into the memory trace that records the event. This is dependent on how much the learner integrates the context with the memories. Smith, Glenberg, and Bjork (1978, as cited in Anderson, 2000) showed the importance of physical context. In their experiment subjects learned two lists of paired words on different days and in different places. Subjects were able to better remember the pairs when they were recalled in the same place they were first learned.

Memory for the to-be-remembered information can also be dependent on the context of other to-be-remembered material in which it is embedded. Thompson (1972, as cited in Anderson, 2000) had subjects study a pair of words such as "blue sky" and were told they would be responsible for recalling only the second word in the pair. Subjects were better at recall when they were presented with the pair of words instead of just the one.

Recommendation Application:

This recommendation will be applied to a computer-generated simulation used for surgical training. Such simulations will allow surgeons to practice hundreds of procedures prior to patient contact, and the practice carries no risk to live patients.

The surgical environment is digitally reconstructed allowing the student to learn in a context that is similar to the context in which the skill will be later applied. For example, the use of a computer monitor during Minimally Invasive Surgery (MIS) simulation replicates the use of a monitor for the actual procedure on a patient. In addition, students can manipulate surgical instruments and receive feedback by viewing the results of these manipulations on a physiological model.

The simulation will also incorporate the use of strategically placed elaborations. As students learn about a particular surgical procedure, the students will be presented will additional information that will enable retention. For example, the simulations will also mimic the look, sound and feel of the real procedure. Digitally created organs will not only look like real organs, they will act like real organs by undulating and reflecting the light when touched, and compress when squeezed or cut.

2. Recommendation: Learners should be provided with feedback and the opportunity to practice/rehearse new information.

Validity of Recommendation:

A memory's level of activation, which determines how accessible a memory will be, is determined in part by how much the memory has been practiced. Each time we use a memory trace it will increase a little in its strength. Strength of a trace is determined by how active it can get, and this accessibility can be increased by repeated practice.

A study by Pirolli and Anderson (1985, as cited in Anderson, 2000) showed the effects of practice. They had subjects practice simple sentences and then examined the effects of practice on the subject's ability to recognize the sentences. The data showed that memory performance improves as a function of practice – the power law of learning. As a memory trace becomes stronger, it can receive more activation, which facilitates retrieval.

Elaborative processing leads to better recall as well as the number of inferences that can be recalled. When students elaborate on material that they are studying they tend to recall more information and recall inferences that they did not study. In studying textual information students should be encouraged to either answer questions while reading or, preferably, generate their own questions.

Frase (1975, as cited in Anderson, 2000) compared the effects of making up questions and the effects of answering them. The results show that when subjects read to in order to make up questions they correctly answered 70% of the relevant test items and 52% of the irrelevant items. When subjects read to answer questions they correctly answered 67% or relevant questions and 49% of irrelevant questions.

Experts seem to display a special enhanced memory for information about problems in their domain of expertise De Groot (1965, 1966 as cited in Anderson 2000). Newell and Simon (1972, as cited in Anderson, 2000) have speculated that in addition to learning meaningful patterns, experts have also learned what to do in the presence of such patterns. In order to develop such expertise in a domain, an individual must spend a great deal of time practicing. Ericsson, Krampe, and Tesch-Romer (1993, as cited in Anderson, 2000) state that in deliberate practice, learners are motivated to learn and not just to perform. Individuals carefully monitor how well their performance corresponds to the perfect performance and where errors occur.

Recommendation Application:

Practice, feedback, and the opportunity for meaningful elaboration of information should be provided to learners during a simulation. In this example, business students will be engaged in an economic simulation similar to the popular "beer game". The student in this simulation will be able to choose between three roles; the manufacturer, distributor, or retailer.

As students engage in the simulation they are able to practice theories of economics and receive feedback on their choices. For example, if the student chooses the role of retailer there is a chance that he/she can become overstocked on a product or he/she might not be able to meet the customers' demands for the product. The simulation would provide the student with the opportunity for practice in various roles and receive immediate feedback in the form of visual representations such as graphs. After extensive practice, students will be able to see patterns (chunks) and make predictions based on those patterns.

In addition, elaboration techniques can be implemented to help students retain information. The simulation can begin with a case study or scenario that will allow students the opportunity to form questions that will be answered during the actual playing out of the simulation. After the simulation students should be given time to reflect on what they have learned and try to answer the questions that they made up with the opportunity to review relevant information. .

3. Recommendation: In addition to lectures and readings, visual aids should be used to support the information being presented.

Validity of Recommendation:

Subsystems of our working memory allow us to process information from different modalities simultaneously. Baddeley and Hitch (1974, as cited in Smythe et al., 1994) proposed that working memory was composed of a central executive and an articulatory loop. The executive controls the use of various slave systems and the articulatory loop that acts a storage device for the rehearsal of information. Baddeley and Hitch were able to show that subjects were able to rehearse digits while at the same time carrying out a reasoning task. These results support the theory that our working memory is made up subsystems.

Evidence for a third subsystem that deals with visuo-spatial material also exists. The visuo-spatial sketchpad allows the storage of images. The Hayes (1974, as cited in Smythe et al., 1994) reported that subjects described "moving" symbols around in their minds and used these symbols for simple mathematical operations. In addition, Frick (1984, as cited in Symthe et al., 1994) found that when subjects were asked to rehearse a set of digits that were presented visually while at the same time rehearsing a set of digits presented orally there was an increase in the span remembered for the mixed condition.

Visuo-spatial and verbal tasks do not interfere with each other as much as they do with themselves. Paivio's Dual code theory (1971, 1986 as cited in Anderson, 2000) states that verbal and visual information are represented in different ways. His research has shown that visual images greatly enhance the memory of corresponding verbal information. The Dual code theory receives support from research conducted by Roland and Friberg (1985, as cited in Anderson 2000), which demonstrates that different neural regions in the brain process verbal and spatial information.

It is important to present visual information so that the learner can retain this information and it is accessible for later recall. An important function of imagery is that it enables us to construct new objects in our minds and these objects can then be inspected. A study by Finke, Pinker and Farah (1989, as cited in Anderson, 2000) shows that we make judgments on these objects and come to the same conclusions as the judgments we could make on seen objects. Wallace (1984 as cited in Anderson 2000) indicates that the imagery system can reproduce a detailed visual representation.

Visual images are important to include in the instructional design rather than just textual/verbal descriptions of objects because individuals will have a harder time manipulating imagined objects versus a visual representation. Kihlstrom, Rose and Gilsky (1992 as cited in Anderson 2000) cite that it is more difficult to rotate an imagined image than a picture. These results show that it seems harder to process an image than an actual stimulus.

Recommendation Application:

When constructing an online learning environment it is important not to rely too heavily on text to provide information to your learners. Returning to the medical example, if an instructor was using a course management system such as Blackboard to teach an online medical course he/she would be able to provide students with recommended texts, links to related articles that might be in PDF form or a word file, and lecture notes in a similar file type. But it is also essential to include visual aids, such as diagrams, pictures, streaming video, and links to web sites that might contain even more visual information about the subject

If the topic of a course includes the human heart students would have a difficult time imaging its structure and function by just reading about it. Students would need visual aids that would enable them to manipulate the heart mentally. For example, students may need to recall what a certain defect look like on the heart and how that would affect its function. Visual aids will also enable students to retain information about what they had read in the course. Photographs, diagrams, streaming video of a real beating heart, or a 3-D representation will provide students with additional ways to cognitively process the information.

4. Recommendation: Information about a topic should be hierarchically organized and broken down into subcomponents.

Validity of Recommendation:

The organization of information presented to learners is very important to the retention of that information. Bower, Clark, Lesgold, and Winzenz (1969, as cited in Anderson, 2000) asked subjects to learn all the words in four "tree" hierarchies and then compared two conditions of learning. These conditions were divided into an organized condition and a random condition. The organized group had a better advantage of recalling the information than the random group. Analysis showed that the subjects in the organized group recalled the tree in order of the tree hierarchy. This systematic recall of going down the tree from the top enabled subjects to cue their memories.

Complex mental images can be organized into chunks, a unit of knowledge representation (Miller, 1956; Simon, 1974, as cited in Anderson, 2000). These chunks combine a number of sub units and they also serve as the basic unit in a larger structure. Evidence also exists for the hierarchical organization of spatial images. McNamara, Hardy, and Hirtle (1989, as cited in Anderson 2000) had subjects memorize the location of the contents in a room. Subjects divided up the room into sub areas and formed separate sub images of the objects in these areas.

Research also shows that subjects store long sequences of information hierarchically which are then divided into subsequences. Klahr, Chase, and Lovelace (1983, as cited in Anderson 2000) looked at how long it took subjects to generate letters in the alphabet subsequences. Recall times were faster if the letter was in the beginning of the subsequence and slower at the end. It is thought that subjects are scanning through the subsequence until the target letter is found.

Recommendation Application:

Returning to the medical example, in teaching a course related to the human heart it would be important to present the information in a hierarchy, which would include the vascular system and other systems of the human body. The hierarchy would provide the learner with cues to recall information about the human heart.

More specifically, to understand the flow of blood in the body it is essential to understand certain hierarchical systems of the human body such as the vascular system and pulmonary system. The next step in the hierarchy is to provide information about which organs make up these systems and then provide information about the individual parts of these organs and their functions. An understanding of how blood flows would require knowledge of the lungs and the individual components of the heart. Finally, the long sequence of events that enable blood to flow can be divided up into 6 subsequences.

A diagram or picture of the human heart should be presented to the learner in a hierarchical structure. A structure of the heart would include its 14 separate components and how they fit together in this structure. When studying such a complex image, students can remember the individual components as chunks as well as their spatial relation to each other.

5. **Recommendation:** While engaging an individual in a learning activity, the learner should not be overwhelmed with competing tasks or unrelated information.

Validity of Recommendation:

Research shows that that it is difficult to retain multiple unrelated memories about the same stimulus. McGeoch and MacDonald (1931, as cited in Smyth et al., 1994) demonstrated that the learning similar information hinders the retrieval of the original set of data learned. These findings are constrained to the remembering of meaningless information, interference does not occur when the memories are redundant

Bradshaw and Anderson (1982, as cited in Anderson 2000) had subjects learn some information about famous people to test the effects of interference and redundancy. There were three conditions; subjects learn a single fact, subjects learn a target fact and two unrelated facts, and subjects learn a target fact and two related facts. Their findings show that recall was better when the subject had learned the two related facts and worse when subjects learned the two unrelated facts.

The learning environment must ensure that modalities do not conflict. Learners can process multiple stimuli at one time as long as two or more stimuli do not require central cognition. Karlin and Kestenbaum (1968, cited in Anderson, 2000) presented subjects with both a visual and a verbal task in which they were to complete the first task and then the second. The delay between the 2 stimuli was manipulated. The results show that at short delays the subjects were delayed in performing the second task due to interference caused by the first task. The interference occurs when the subjects must encode an auditory stimulus, which requires them to finish the first task. This central bottleneck will occur if we require learners to think about multiple things at once.

Recommendation Application:

A course designed to instruct medical students about heart disease would need to present information to the learner that is specific to this topic. Presenting related information about heart disease will strengthen the individual's memory trace, but presenting unrelated information would interfere with the individual's ability to retain information. For example, if discussing the link between smoking and heart disease the information should be constrained to the heart and not to other effects of smoking, such as lung cancer.

In a multimedia learning environment, it might be tempting to include as many different learning opportunities as possible such as streaming video, audio, and animated graphics. The instructional designer must be careful not to require the learner to engage in two activities simultaneously that would create a "bottleneck" for the learner. For example, the learner can be presented with a brief textual description of a particular heart aliment and then shown a video of an actual heart with this condition, but a learner would be unable to retain information if he/she were required to read the text and view the video at the same time.

6. **Recommendation:** When creating multimedia-learning environments, careful consideration should be given to the construction and use of graphics so that they can be easily perceived and processed by the learner.

Validity of Recommendation:

Cognitive theories of how we perceive objects are important to the creation of realistic graphics used in instructional technology. It is important in such learning environments that the representations of objects be as realistic as possible, which requires a great deal of consideration into how we perceive the world. David Marr (1982, as cited in Anderson, 2000) proposed the term 3-D model to describe how visual cues combine to create a representation of the locations of surfaces in three-dimensional space. These cues include texture gradient, elements appear closely packed together as the distance from the viewer increases, and stereopsis, an individual's two eyes receive slightly different information about the world. Another cue involves parallax, as more distant points move they will move slowly across the retina than closer points.

Object perception and object recognition are also important principles in the creation of visual aids. Object perception considers how Gestalt Principles of Organization influence how we perceive objects. Palmer (1977, as cited in Anderson, 2000) found that when subjects were asked to recognize parts of figures they could distinguish the parts most rapidly when they were the segments predicted by the gestalt principles. Object recognition is the idea that a familiar object can be seen as a known configuration of simple components.

Visual attention of the learner is another critical factor to consider when presenting information. Erikson and Erikson (1974, as cited in Anderson, 2000) concluded that narrowing our visual "spotlight" gives maximal processing to that part of the visual field but it takes time to shift attention to a different part of the field. Since learners fixate on the portion of the visual field to which they are attending, it is important not to overload the monitor with too much visual information that will compete for the learners' attention.

In addition, since we have brief visual memories, learners must be given time to attend to information displayed otherwise it will quickly fade from memory. Sperling (1960, as cited in Anderson 2000), through a series of experiments, demonstrates that visual information is held in a brief sensory store, but unless we attend to it and process it further, it will be lost. While designing a multimedia-learning environment it is important to give learners enough time to attend to the visual information being presented.

Recommendation Application:

Realistic 3-D simulations are frequently used to provide training that would be impossible or dangerous in a real setting. It is important that the environments and objects of a simulation are as realistic as possible. In constructing a 3-D object to simulate the human heart, designers must consider how individuals perceive the world. Cues such as texture gradient and parallax must be employed as well as gestalt principles of organization.

How visual material is presented to learners in a multimedia-learning environment is also important. The learner should not be overwhelmed with multiple objects on a screen that compete for attention. Visual material should be presented so that individuals can focus their attention on one area of the monitor. For example, when presenting students with a visual representation of how the human heart pumps blood the student's visual attention will be directed to the particular part of the heart being used. It would be ineffective to introduce a competing visual representation in a different location on the monitor because the student will be unable to focus adequate attention on both visuals. In addition, learners should have enough time to process the visual information presented.

Abstract: The website cells.de offers learning objects for cell biology as a teaching and learning repository. We wanted to find out whether we had been able to address diverse target groups in the teaching and learning process with our offering. Using log files, a questionnaire and usability tests, we found that students and pupils used the website as a resource for learning, while lecturers and teachers used it mainly for presentations and projects. We were also able to show that we could address users in different countries.

Introduction

Production of high quality E-Learning material is expensive, and may well cost 50.000 € for one hour of usage (Schulmeister 2001). Costs per user may be reduced if it is possible to address multiple target groups at the same time. To contribute to the discussion in this economic and pedagogical important field, we therefore evaluated a website about cell biology which is targeted at diverse users. We wanted to find out whether we were able to address diverse target groups in the teaching and learning process, particularly students, pupils, teachers, professors and laymen, using our website as a teaching and learning repository. In Germany we already had observed that pupils of the high school in the year 11 to 13 in special courses in biology had to deal with similar learning objectives as had students at university level in introductory courses in biology (Bereiter-Hahn 1998). Thus, we thought it possible to address students and pupils using only one teaching and learning repository. Additionally, the learning objects of our teaching and learning repository were produced so they would not only be suitable for students and pupils, but also for high school teachers in the year 11 to 13 in special courses in biology and university professors in Biology. As an additional target group we envisaged private users that have an interest in cell biology for a variety of possible reasons. Having published our website in German and English language, we also wanted to find out whether we were able to address users in countries were German or English is the native language, or in countries where the knowledge of English is well developed. We thought it plausible to address learners and teachers in different countries; the basis for this expectation was our observation that cell biology teaching and learning is not influenced strongly by regional or cultural factors.

Description of the website

The website cells.de (see www.cells.de) is maintained by the German IWF Wissen und Medien gGmbH (see www.iwf.de). IWF is an educational institution that has an assignment in higher education. It provides audiovisual media for higher education. From 1998 to 2002, in co-operation with the Bio center at the University of Frankfurt and two private companies, IWF build up a comprehensive media archive for cell biology. This was conducted in the context of the German Federal Ministry for Education and Science funding for the "further development of the scientific and technical book for multimedia knowledge representation". The project's objective was the progressive preparation and application of an interactive knowledge representation in cell biology – a modular media service.

The website cells.de is one major offspring of this project. It was launched in April 1999 and continuously improved since then. It contains digital media in Internet quality as well as additional information for university and school on the subject of cell and molecular biology. Collections of links exist to learning and teaching material, dictionaries and documents on experimental exercises, journals and occupational information. Searching aids and a lexicon are integrated, as are FAQ (frequently asked questions) and a guest book. Digital media are the main component of "cells.de". 132 videos and animations in QuickTime and RealVideo video format and 3D objects (QTVR) are offered in German and English language. Additionally 41 shockwave animations (computer animations and interactive learning modules) are available in German language. These digital media are available for free in full-length versions. They are specially prepared for the purpose of teaching and learning at universities and schools.

Thematic foci of the website are plant cells, animal cells, cell types, cell structures and cell functions. Several didactical and pedagogical approaches were used when producing the learning objects. Introduction, explanation, consolidation and review of learning objectives are generally presented using audiovisuals, particularly short videos or animations, combined with audio presentation of text. These presentations generally are used to visualize processes. Rotateable 3D-models and 3D-animations are used to visualize structures. Besides these presentations, learning tasks are offered using Shockwave animations. Learners can work through interactive computer animations, e.g. by clicking on a distinct part of an animation to select the correct answer.

Methods

Log files

For the structural analysis of the groups of users we used assessment of log files and a questionnaire. Log files from Mai 7th to June 30th 2002 were downloaded from the server at IWF that hosted www.cells.de. They were analyzed with Web Trends Log Analyzer 6.0. The log files were stripped of visits caused by co-workers of the IWF and of visits by roboters, spiders and crawlers, thus eliminating visits that do not stem from users that access the website searching for information. We registered 227,824 successful hits on the entire site and 19,900 visitor sessions. Visitor sessions were considered terminated when no activity were detected for 30 minutes. Log files for 5 days were missing due to technical reasons.

Questionnaire

A questionnaire was constructed with ten sets of questions for the German version, and eleven questions for the English version of the website. One set of questions used free text as an answer ("what did you like about…"); the other could be answered by choosing an already prepared answer. The questionnaire could be filled in online. It was linked on the German and English start page of www.cells.de from Mai 7th to June 30th 2002. 38 German and 27 English questionnaires were filled in. Cluster Analysis was performed with SPSS 11.0 for Windows using the algorithms "single linkage" and "average linkage between groups".

Usability Test

To find out if users were able to use the website, a usability test was performed in cooperation with the company eResult GmbH in Göttingen, Germany. To find people with an appropriate profile, participants were acquired using an Online-Access-Panel. Three students of Biology or Medicine, three pupils (high school), one teacher and one lecturer participated. The behavior of participants was recorded using following steps:

- First contact with the website and rummaging around, behavior of participants recorded with the site covering method as described by Wilhelm 2002 (10 minutes)
- Focused intense interview (10 minutes)
- Scenario based testing: searching for content (20 minutes)

Findings

From Mai 7th to June 30th 2002, 19.900 user sessions were registered on cells.de by log files. These visitors downloaded or streamed 12.360 videos and 3.154 Shockwave files. For example, the video "Plasmolysis - Epidermal Cells: Onion" was requested 241 times, the QuickTime VR object "Rotateable Plant Cell: 3D model" 118 times and the video "Flagellar Motility - Euglenoid" 111 times.

The questionnaire carried out in this period indicated that students were the major user group of cells.de (35%), followed by teachers (26%) and pupils (19%). Learning was the main motivation of the users (60%), but the website was also used to rummage around (32%), for presentations (29%) and project work (21%). Cluster analysis indicated that lecturers and teachers used the website mostly for presentations and projects, while

students and pupils used it for learning. Even if only 9 % of visitors saw themselves as private users, use at home (58%) was dominating the use at universities (33%) and schools (22%). Most of the users have been visiting the website for the first time (45%) or have been visiting it only for a few times (42%). 88% of the users had a good or very good overall impression of cells.de. To find the website in the Internet, search machines (45%) were more often used than links (26%) or suggestion of teachers or lecturers (22%). 64% of the visitors questioned came from the German speaking countries Germany and Austria, while 36% originated from other countries. This finding is supported by the analysis of log files: 63% of the visitors use the German version of the website, while 37% use the English version. The questionnaire showed that visitors from the United States (15% of the overall users) are the most frequent non-German visitors.
The majority of tested users in the usability test thought that the start page was structured clearly (after the first contact with the website and after rummaging around for 10 minutes). However, the intention of the site was not understood at the first glance. Only half of the users realized immediately that multimedia learning content could be requested. The overall structure and classification of the available multimedia content about cell biology was considered to be usable by a majority of test users. However, it was criticized that some pages with a lot of information had to be scrolled, and at first glance were confusing. In a scenario based testing the participants were asked to search for a video about cell division. Several retrieval methods were available: two search engines, browsing and a site map. Four users were able to find relevant multimedia content at once; two needed a second try, then using alternative retrieval methods. Two users needed external help to find relevant multimedia content. After the tests, 7 of 9 test users said that they wanted to use cells.de again.

Conclusions

We wanted to find out whether we had been able to address diverse target groups in the teaching and learning process using our website as a teaching and learning repository. We could demonstrate that the website attracted a substantial amount of visitors that downloaded the available multimedia learning objects. Students and pupils found the website to be a valuable resource for learning, lecturers and teachers for presentation and projects. This indicates that these target groups could use the offered multimedia learning content in the teaching and learning process. An overall usability of the website could be demonstrated, even if the tests carried out with students, pupils, lecturers and teachers showed a few weaknesses when navigating in the website. Thus we could show that we were able to successfully address different target groups. We also wanted to find out whether we were able to address users in different countries. Even if most visitors came from German speaking countries, we were also able to address a substantial amount of international users, in particular from the US. Further research has been initiated to find out in more detail how the offered learning objects are used in the learning and teaching process (Huk 2002).

Workplace Environments Are Evolving: Is Adult E-Learning Keeping Pace?

Michael Ellis Scheuermann
Drexel University
michael.scheuermann@drexel.edu

Abstract: Modern organizations are evolving into dynamic workplaces, challenging employees to become involved in new, exciting ways. *Reengineering* challenges employees to embrace roles that are evolving as quickly as their organizations. New roles provide *empowerment* for employees who become increasingly *self-managed* within these *learning organizations*. Personal growth is not only initiated and nurtured – but expected. More of these employees are entering our virtual classrooms, welcoming the opportunity and challenge that higher education represents. The focus of this paper is whether educational institutions are up to the task. Have they evolved as other modern organizations? Are they prepared to extend through e-learning the work that learning organizations began? Is higher education up to the challenges that these individuals bring from their workplaces into our virtual classrooms? Moreover, are we as e-learning educators prepared for these dynamic, empowered, and self-managed individuals?

Today's adult students engaged in e-learning are often professional men and women who work for a living and take college courses via the Internet. As employees during the day, these individuals face workplace roles that have been evolving rapidly. First, they are often involved in *self-managed teams*. Second, they are *empowered* as employees within their organizations. Third, firms have been undergoing *reengineering* wherein organizations evolve into flatter configurations with far fewer reporting levels, thus expecting employees to take on additional responsibilities. Fourth, *participative management* in organizations is an emerging concept enabling more men and women to determine what decisions should be made, with little, if any, upper management intervention. Fifth, one of the key tenets of managing and orchestrating *change* in organizations today is to involve workers from all levels in change initiatives, as early as possible in, and then throughout, the process. Finally, these men and women find themselves working then in what Senge (1990) termed *learning organizations*, where new ideas are needed, knowledge must be transferred, and behaviors must change.

These substantive organizational developments represent considerable challenge to educators. They are suddenly faced with an evolving set of expectations from their adult students. At work, these individuals are taking charge of their own careers and their own organizations on a broad-based, multi-dimensional, and escalating basis. They expect to be able to do the same in their virtual classrooms. Organizations are not merely *enabling* employees to participate in new ways. They are *expecting* these men and women to perform in myriad evolving initiatives. Hence, when these individuals engage in e-learning as adult students, we, as instructors, need to determine how to participate most effectively with them.

After long, often difficult, and challenging workdays the last thing these nontraditional students need is an academician who is going to unilaterally direct their learning. In these settings, we, as educators, can, instead, leverage the workplace experiences that these individuals have just had, building upon them across their e-learning courses. Kidd (1973) called this the art of learning rather than schooling. Livingstone (2001) noted that in this information age there is more knowledge accessibility in our learning society within which workers can extend their learning. Adult learning theory includes the need for nontraditional learners to participate in the formulation of their learning in order for that learning to be most effective (Brookfield, 1986). This concept aligns with the experiences these nontraditional students have throughout their workdays.

Moreover, Friere (1970), Houle (1996), and Mezirow (2000) determined that adult education must include some element of empowerment, while Dewey (1926) said that education must be a constructive process rather than a passive activity. Kidd (1973) spoke about the *learning transaction*, where students must be involved in the process. Knowles (1990) envisioned shared learning enmeshed with shared authority. Collaborative teaching and learning (Conti, 1978) has been found to be a significant component of adult learning theory. Instructional models formulated by Merriam and Caffarella (1999) included both student self-direction and control of their own learning. Houle (1996) described education as a *cooperative* rather than *operative* art that functions in a facilitative way. Rachal (2002) investigated concerns regarding learner control. Solomon (2001) observed that negotiated content and activities were integral to learner-centered pedagogy. According to Sgroi (1998) it is the students' responsibility to direct their own learning while Peters and

Armstrong (1998) referred to the teacher as a member of the group of learners, a participant in collaborative learning. Brookfield (2000) stated that learners and facilitators cooperate in the learning enterprise on curriculum, practices, and objectives.

In their careers today, these individuals are expected to take control in order to improve their workplace performance. They are *empowered, self-managed*, and integral to *reengineering* and *change* processes within their new *learning organizations*. Simply put, they are *involved* and *engaged*. As educators, developing and delivering e-learning courses for adult students, we can leverage the strengths that these students develop during their workdays. We can utilize them to enhance the e-learning environment and experience, for ourselves and our students. We can, to the greatest practicable extent, (a) involve them in the development and construction of the e-learning courses, (b) focus on learning rather than schooling, (c) empower students in our courses as they are empowered in their workplaces, (d) share our authority and control, (e) collaborate with students from development, through delivery, to evaluation, (f) incorporate self-directed learning, (g) facilitate rather than dictate, (h) negotiate course content and activities, (i) challenge students with heightened responsibilities, (j) engage learners, (k) increase our participation with them, and (l) cooperate with students all across our course timelines.

E-Commerce Privacy and Security: Degree of Awareness Among College Students

Abstract:

Two main issues related to the participation in electronic commerce are the assurance to consumers that their transactions are secure and their privacy protected. Very little information is available about consumer awareness of safeguards to protect them from privacy and security related frauds. The proposed experimental study will create simulated e-commerce web sites (one secured, one unsecured) to find out the degree of awareness and knowledge of college students about the privacy and security of their transactions. Once the student logs on to the computer, she is randomly assigned to one of the two versions of a web site dividing the sample in two groups. The sample will be drawn from students taking classes with the researchers during the Fall semester of 2002. Descriptive statistics and Analysis of Variance will be used to analyze the data. The findings of this study can be used for consumer education and public policy recommendation purposes.

Introduction:

On-line shopping has increased dramatically during the past decade. According to the CommerceNet/ Nielsen Internet Demographic Survey, Internet users over the age of 16 in the United States and Canada increased by 59% from 57.8 million in 1997 to 92.2 million in 1999 (http://www.commerce.net/research/stats/wwwpop.html). The latest Forrester Online Research Index shows that consumers in the United States spent nearly $4 billion on line during the month of July 2001 (http://www.forrester.com/ER/Press/Release/0,1769,621,00.html).

Along with the advantages brought by electronic commerce for consumers, several concerns have been identified. Two of the main issues are related to the assurance of privacy and security of on-line transactions (Briones, 1998; Caudill & Murphy, 2000; Miyazaki & Fernández, 2001;). The Federal Trade Commission (FTC) conducted a study in 1998 where 1,402 commercial web sites were analyzed to "determine whether self regulation is an effective means of protecting consumer privacy on the Web". They found that a variety of personal information is collected from consumers such as "name, e-mail address, postal address, telephone number, fax number, credit card number, Social Security number, age and date of birth, gender, education, occupation, income, hobbies, interests, and the type of hardware and software used by on-line consumers". The information collected may also be released to, or accessed by, third parties compromising not only privacy, but also security. Furthermore, the FTC found that only a small number of the Web sites surveyed offer either a Privacy Policy Notice or an Information Practice Statement where consumers are informed about the use of the information they provide. (http://www.ftc.gov/reports/privacy3/survey).

Based on their study, the FTC recommended legislation to provide basic standards for the collection of information on line (Newsweek, 2000). In response, web developers and on-line businesses through entities such as the On-Line Privacy Alliance and the Platform for Privacy Preferences or P3P, argued against additional legislation and provided self regulation alternatives in the form of third party seals of approval and voluntary Private

Policy Statements (http://www7.software.ibm.com/vad.nsf/Data). Some of the privacy and security related third parties seals of approval include the Better Business Bureau, CPA WebTrust, TRUSTe, VeriSign, and Web Assurance Bureau (Miyazaki & Fernández, 2001).

Regardless of the outcome of this debate (legislation vs. self regulation) the assumption is that consumers do read, understand and use the information about privacy and security provided on the web site before they decide to make an on-line transaction. In other words, consumer awareness of these safeguards is an assumed condition that may not always be present. This is a research problem that merits investigation. Furthermore, if educated, technology oriented consumers; such as college students, show that the assumption is incorrect, then it can be argued that consumer education on topics of privacy and security on on-line transactions need to be addressed as part of the discussion related to regulation.

Objectives:
In order to investigate privacy and security issues, the proposed experimental study will create simulated e-commerce web sites (one secured -Group S, one unsecured- Group U) to answer the following research questions:

1. Do college students involved in an e- commerce transaction recognize and use security and privacy protection devices (private policy notices, seals of approval, etc.) within the site?
2. How do the provision of security and privacy protection devices influence purchasing decisions among the students?
3. Is the amount and type of information provided by students doing an on line transaction using a "secured" site different from the amount and type of information provided by those students using an "unsecured" site?

Methodology
Sample:
Students from the Departments of Technology and Family and Consumer Sciences enrolled in courses with the investigators during Fall 2002 (5 courses) will be invited to participate in this study. The sample will include approximately 100 students in their junior and senior years.

Experiment:
All participating students will logon during their regular class time to an e-commerce simulated website offering products and services such as CDs, clothes or travel. Students will be informed that the web sites are simulations, however they will be encouraged to treat the transaction as a real one. Furthermore, the web sites will be designed so that participants a) can access the web site for only one transaction and b) can not go back to change data once they have completed the transaction or have decided to prematurely terminate it.

As students logon to the website they will be randomly assigned to two almost identical web pages. One group of students (Group S for 'secured) will be 'connected' to a web page that represents a secured version of an e-commerce company as indicated by safety symbols of Certification Authorities such as WebTrust, TRUSTe and VeriSign. In addition to the symbols of the Certification Authorities, the web page will contain a privacy statement with carefully stated Privacy Guidelines. These guidelines will include statements about:

- sharing customers' information with other companies;
- tracking customers as they move around the site;
- capturing information not related to the purchase such as SSN;
- capturing survey information;
- providing ways for customers to discover and change information collected from them.

The second group (Group U for unsecured) will be 'connected' to a version of the web site that will not contain the safety symbols of the Certification Authorities provided on the web site for Group S nor the privacy statements.

The formation of two distinctive groups based on the creation of two 'almost' identical web pages will allow the researchers to test the hypotheses and to address the research questions discussed above.

Instrumentation and data collection:

As the students do their transactions, they will be asked to provide personal information. The information requested some of which is unnecessary for the transaction, will include:

- name, e-mail, postal address
- telephone and fax numbers
- credit card number(s)
- Social Security number
- Age, gender, date of birth
- education, occupation, income
- hobbies, interests.

As soon as students have completed or prematurely terminated the transaction, they will be led to an on-line evaluation tool to answer a questionnaire that will collect demographic information such as age, class rank and major. Additional questions will assess students' awareness of the safety symbols and privacy statements used on the experimental website. If students decided to terminate the transaction before completion, they will be asked to provide reasons.

In addition, the transaction itself will serve as part of the instrumentation. For example, the decision to provide the SSN or credit card information will be automatically recorded. A database will be created with this information.

The following data will be collected to address the objectives of this project:

- number of students from Group S that accessed both the safety symbols and the privacy statement provided on their secured website;
- number of students that terminated their on-line transaction prior to completion and

- amount of personal data (such as Social Security Number, credit card information, etc.) that was provided by students from either group.
-

The methodology and instruments will be submitted for approval to the Institutional Review Board (IRB) for Human Subject of Illinois State University.

Statistical Analyses:
The Statistical Analyses will include descriptive statistics such as frequencies, and percentages as well as analysis of variance (ANOVA) to compare Group S and Group U with respect to a) the use and knowledge of safety symbols and privacy statements, b) premature termination or completion of the transaction, and c) amount of personal data provided in their e-commerce transactions.

It is expected that the findings of this study can be used for consumer education and public policy recommendation purposes. With these goals in mind the results of the study will be disseminated through scholarly publications and presentations. It is recognized that the use of technology by consumers in their market transactions is a relatively new area of research with a number of unanswered questions open for future investigation.

A Dose of Reality in the Classroom

Diane M. Schuch-Miller, Greenfield Coalition, Wayne State University, USA, schmild@focushope.edu

Marie D. Lee, Greenfield Coalition, Wayne State University, USA, leem@focushope.edu

Abstract: The engineering education community is demanding that Engineering graduates are better able to solve problems. However, traditional lecture does not allow learners to engage with and manipulate new knowledge and skills in preparation for application in situations other than those described in textbooks. Reality-based learning (RBL) is the approach adopted by Greenfield Coalition (GC). This paper discusses the methodology for designing RBL activities as well as several examples.

The Need for and Value of Reality-Based Learning

One of the challenges of engineering education is that students are not able to extrapolate information from a textbook problem to the real world experiences of an engineer on the job. This is due, in large part, to the lecture style of teaching and learning which does not allow learners to link the new information to a familiar context. Furthermore, it does not allow students to test their own hypotheses and discover through their own experiences. The difficulty, then, is to identify other instructional methods that are better able to develop critical thinking, problem analysis and decision-making skills. At the Greenfield Coalition (GC), the answer has been reality-based learning (RBL).

No matter what your feeling on reality-based television might be, the "reality-based" theme has application and value in the classroom. Students often ask the question, "Why do we have to learn this?" Reality-based problems present content and concepts in real world contexts. The "why" is apparent throughout the activity. The question then becomes, "How can this problem be solved?" How will the learner solve the problem at hand? What materials in the textbook, on the Internet, in the instructor's direction or in the brains of peers will be essential for completing the activity?

Used by medical schools for years, this immersion approach of reality-based learning gives students the ability to apply new knowledge and skills in a manner that, based on their prior experiences, makes sense. In doing so, learners test theories and make unique connections to previous knowledge. This method lets students organize the new concepts in a more logical and relevant framework.

Instructional Design for RBL

RBL can be designed and utilized in multiple disciplines. Concepts in a text or lecture can be transformed from words on a page or in the air to active, participative, discovery problem-solving. By "doing," retention and transfer of knowledge and skills dramatically increases. To create an activity for RBL, a performance-based objective must be explicitly stated. Then, a suitable assessment method must be identified. Finally, an activity that allows the learner to meet the assessment can be crafted and implemented.

A well-written, performance-based objective should contain four components: audience, behavior, condition, and degree, often referred to as ABCD. These objectives state observable, measurable behaviors to be demonstrated by the students upon completion of a learning segment.

A natural choice for assessment with reality-based learning is authentic assessment. Authentic assessments test the learner in a capacity beyond a paper and pencil examination. In the real world, students will be challenged to make decisions, solve problems, use tools, and discuss with their peers. They will be assessed by their company and customers in the work they do. Besides the instructor, assessment in the classroom can come from work supervisors, peers, and even the student. Ideally, authentic assessments should depict actual on-the-job tasks or deliverables and therefore, can take the form of a product design, process implementation, presentations, discussion participation and a myriad of other possibilities. Once a performance-based objective is identified and an authentic assessment method is determined, a RBL activity can be created for the learning application.

Reality in activities comes from problems that do, have, or might occur in the real world. At the Focus: HOPE Center for Advanced Technologies (CAT), candidates work and learn in the same environment. During the day they participate in manufacturing engineering operations, such as machining, sales, purchasing, engineering design and shipping, for a t ier one supplier to the automotive industry. For students in a more traditional educational setting, the real world can often be simulated through computer-generated graphics and animations, a collection of written documents, transcripts and videos of interviews, still and moving images, or through examination or investigation of their own environment.

Consider solving an economic depreciation problem in a textbook. This method allows students to practice the calculations only. Conversely, an activity, using Microsoft Excel – an authentic tool, requiring the selection of the best method of depreciation considering the tax implications to the company – not only provides practice, but also provides for the application of knowledge and skills in a situation hat has a real impact, greater meaning and provides a richer context for learning than a textbook problem.

RBL Examples

At GC, RBL is utilized throughout many courses. Following is a set of examples from several courses.

Students learn about the launch of a new product by applying each phase of the process to a mechanical pencil. This allows them to familiarize themselves with the process by doing rather than reading about it. Furthermore, process maps and templates used by engineers are included in the course materials.

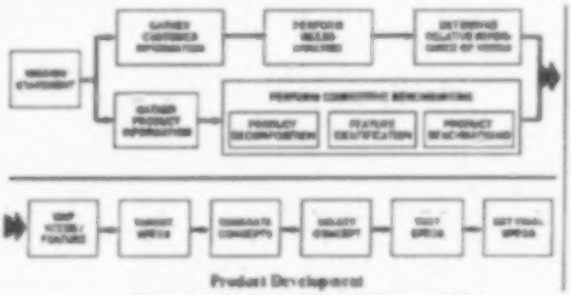

Figure 1. Product Launch Process Map

In a course on engineering economics, a capstone case analysis necessitates the application of techniques and decision-making tools presented earlier in the course. In this case, a situation is used from the CAT where shipping deadlines for pulleys are missed due to delays in the balancing operation. A wealth of resources is provided for students to begin their investigation. Further, WWW links are included to trigger research as deemed appropriate by the learner. The final deliverable for this case is a recommendation for resolution to the situation. A thorough analysis of alternatives, including a decision tree, must be included in this report. A presentation to Focus: HOPE management is also an expected outcome.

To support courses in Tool Design and Construction, Engineering Economics, and Manufacturing Systems, comprehensive case studies in manufacturing have been crafted. One of these studies examines the instability of boring tolerances in a turned pulley. It is difficult to determine exactly what causes the irregular measurement, however, this is the precise challenge for the student investigating this case. These situations depict real challenges faced by manufacturing engineers.

Figure 2. Pulley Process Map for GC Case Studies

In courses focusing on tool design and machining processes, technology is used to represent machining processes that are more difficult to view up close and in person. Here, a turning operation is depicted. Students can view either an animation showing a detailed perspective of the turning process or a video showing the broader view of the part, the machine, and its surrounding environment.

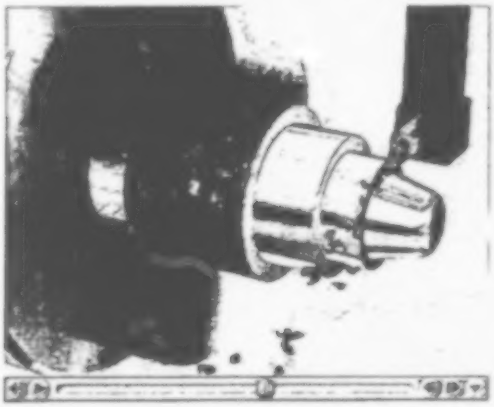

Figure 3. Animation of Turning Process for GC Courses

The concept of cycle time is discussed in manufacturing systems and operations management courses. In both courses, learners use a computer-enabled simulation to move machining centers around a virtual shop floor. Following the movement of each machine, students can run the production line and see the impact of each machine on the overall output of a production line.

BEST COPY AVAILABLE

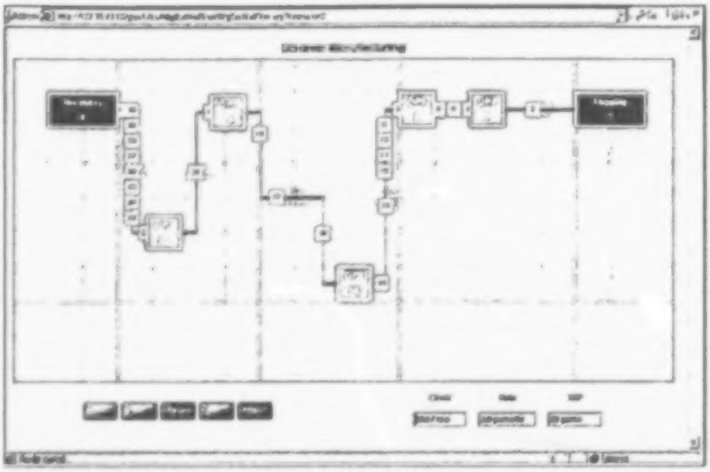

Figure 4. Discrete Manufacturing Simulation for GC Courses

The above mentioned examples are just a few of the reality-based learning activities at GC. Other examples involve observing data from the General Motors Crossover line to examine the concepts of variability of data and the effect of randomness. A set of experiments is being designed to support courses in thermodynamics and thermophysics. In a course on the business aspects of the manufacturing organization, students examine how departments work together through the implementation of a role-play simulation that involves classroom interaction as well as online participation.

Content Management

The online component of GC courses is specifically designed to be independent and transferable to other teaching and learning institutions. By using an object-oriented, asp-driven database structure, GC can deliver only the portion of the course, session or activity that is desired by others.

Implications/Conclusions

Applying their knowledge and skills to real situations gives students greater confidence in their abilities. The experience of working on real situations and data gives them valuable experience and sets their expectations for working in the field. Students genuinely appreciate the shift in the teaching and learning environment, and the result is a motivated, interested and active learner.

COLOR-CODING REDUCES MEDICAL ERROR: E-LEARNING & THE BLENDED APPROACH

Terry A. Seelinger, MHA, e-Learning Manager, Corporate Information Services, Duke University Health System, Durham, North Carolina, USA terry.seelinger@duke.edu

Karen H. Frush, MD, Medical Director, Children's Services, Duke University Medical Center, Durham, North Carolina, USA frush002@mc.duke.edu

Abstract: The healthcare world faces a challenge for which Blended Learning is a natural fit. How does a large organization deliver just-in-time plus ongoing training and education to a geographically dispersed population with different needs and learning styles who cannot leave their posts for very long? Duke University Health System employs a learning management system and applies Blended Learning as a strategic approach to delivering content at all levels. One element of this effort trains users in a simple color-coding system for pediatric patients that allows them to quickly and easily arrive at the appropriate level of medication, radiation, or equipment size. E-learning for color-coding delivers content in a blended solution that meets the variety of needs and fits the many learning styles of professionals at Duke.

The health care world faces a challenge for which Blended Learning is a natural fit. How does a large organization deliver just-in-time plus ongoing training and education to a geographically and professionally dispersed population with different needs and learning styles who cannot be away from their posts for very long? Duke University Health System (DUHS) employs a learning management system and applies Blended Learning as a strategic approach to delivering learning content at all levels. Blended Learning uses a multi-level approach to combine aspects of online and face-to-face instruction, ranging from static reference material on a web site through self-paced content available at the user's convenience to asynchronous or synchronous, instructor-led sessions via the web.

A prominent project currently underway at DUHS brings Blended Learning to pediatric care as a comprehensive approach to a multi-disciplinary endeavor aimed at reducing medical errors. This widespread effort encompasses areas such as:

- Emergency care
- Bio-terrorism, chemical warfare and disaster response
- Radiation exposure reduction
- Injury reduction

At the core of this effort is a simple color-coding system that allows providers to quickly and easily arrive at the appropriate level of medication, radiation, anesthesia or equipment size for their young patients. E-Learning for color coding delivers content in a blended solution that meets the variety of needs and fits the many learning styles of the professionals at Duke.

Background

Providers recognize the significant problem of medical error in health care, and recent efforts to determine the frequency and severity of errors have yielded alarming results (Lesar, Lomaestro & Pohl 1997) (Leape, Brennan, Laird et al. 1991). Studies have demonstrated that many mistakes are directly related to adverse drug events (ADEs), (Bates, Boyle, Vander Vliet, Schneider & Leape 1995) (Thomas et al. 2000) and medication dosing has been shown to be the stage in drug therapy which contributes most heavily to ADEs (Bates et al. 1993) (Bates, Cullen, Laird et al. 1995) (Leape, Bates & Cullen 1995).

Errors abound in pediatric medication dosing, largely because of conventional dosing methods (Jonville et al. 1991) (Skaer 1991) (Lesar, Briceland & Stein 1997). Healthcare providers are trained to calculate medication dosages using mathematical equations, based on the size of a child, and this calculation step has been pinpointed as a high error activity (Rowe et al. 1998) (Lesar 1998) (Koren et al. 1986) (Kausahal, et al. 2001) Pediatric care is often the most error-ridden of all hospital services (Potts & Phelan 1996), with the emergency department coming in a close second. Time constraints associated with emergency care contribute to medical errors and several factors compound the risk of error when pediatric care must be delivered emergently:

- The need to estimate patient data, which may be unavailable at the time of the emergency, for input into medication dosing formulas. Patient weight, for example, is critical in dosing formulas, but evidence suggests that both physician and nurse estimates of children's weights are unreliable (Harris et al. 1999).
- Limited opportunities for prescription monitoring.
- Lack of pediatrics-trained emergency providers,
- Inability to rely on standardized dosing (i.e. adult ampule),
- Lack of familiarity with proper equipment sizing in children,
- The stresses of managing a life-or-death scenario involving a child
- The overall time limitations affecting each step from assessment to treatment.

Emergency care protocols require rapid delivery of care, but clinicians faced with tasks such as calculating dosages, or changing formulations to deliver the appropriate *concentration* of a medication cannot focus on the priorities of emergency treatment protocols.

Pre-calculated medication dosing charts and "code" cards have been used extensively to reduce error, but the child's weight must be known before the cards can be used. The only method currently available to estimate a child's weight *and* determine correct medication dosage and equipment size is the Broselow Emergency Tape (Lubitz et al. 1988).

In the early 1980s, James Broselow, an emergency medicine physician from North Carolina, developed a simple tool to increase the accuracy of weight estimation in children using established height-weight correlations from the National Center for Health Statistics (NCHS) (Hamil et al. 1979). The Broselow Emergency Tape established length measurements as an accurate method for predicting equipment sizes (based on endotracheal tube sizes and drug doses) for children in emergencies when weight measurements were impractical (Lubitz et al. 1988). The tape was length-based and grouped children, according to height, into color-coded zones for equipment selection. Each color zone contained kilogram body weight increments for medication dosing. Thus, a single length measurement provided emergency equipment selection information (color) and pre-calculated drug doses by kilogram increments. The Broselow Emergency Tape was well received and widely distributed across the country to EDs and EMS agencies, primarily through EMSC grant-related efforts.

As the tape was introduced, a Pediatric Emergency physician from Florida, Robert Luten, was working on a similar concept. Luten recognized the importance of the "zone concept" for medication dosing and other size-related variables, as well as equipment sizing (Lubitz et al. 1988). His research led to the creation of a color-coded tape with appropriate equipment sizes for seven different color zones. As the color-coding concept was further developed, Broselow and Luten worked collaboratively to revise the color zones on the original tape to new zone boundaries derived from more recent data. Drug doses determined by the new zones are, on average, less than 3.1% different than doses calculated from an individual patient's weight (Luten et al. 2001) This value is clinically insignificant for emergency drug dosing, especially when accurate single kilogram patient weights are unobtainable.

The revised Broselow-Luten Pediatric System (B-LPS) simplifies the complex problem of treating a child in an emergency. The zone color provides a single marker that allows access to many therapeutic modalities, including pre-calculated medication doses, pre-determined equipment sizes, fluid volumes, ventilator settings and other size-related variables. B-LPS zones also help prevent "downstream" errors (those that occur after a correct decision has been made in the resuscitation process) by providing a constant reminder of the patient's specific color (and thus the appropriate equipment size and medication dose). The B-LPS allows emergency providers the convenience of a standardized, unit-based *system* without the distraction of estimation, calculation or formula identification. The emergency treatment team then can focus on larger assessment and treatment decisions.

Color Coding Project

In the most immediate manifestation of the color coding initiative, Duke is collaborating with colleagues in Texas and New Jersey on a federal grant where the overall goal is to develop and evaluate an educational program to increase appropriate use of the Broselow-Luten Pediatric System and decrease medical error in the pediatric emergency setting. The program is being evaluated throughout the development cycle, using formative and process evaluation techniques. Primary outcome measures include medication dosing errors, equipment sizing errors and time to implementation during simulated events. Provider comfort level is assessed as a secondary outcome measure using surveys and scripted interviews after participation in the program.

One of the objectives of this project is to develop curriculum for multidisciplinary emergency providers using three delivery methods: printed, CD-ROM and web-based, to allow participation by units/agencies/facilities with all levels of technologic resources. The content developer has drafted the educational training program, consisting of the theory of B-LPS, development of color zones, and the concept of zone dosing vs. conventional dosing calculations. Learning objectives have been collaboratively developed with an advisory group to target the needs of the pilot populations. Core content is delivered using several different methods, based on the resources available at learning sites, and allows students to choose learning methods best suited to their learning style, while also allowing full utilization of locally available computer resources:

- Printed materials for participants who have limited or no computer access.
- Distributable CD's for participants with computer access but no Internet connectivity.
- For sites that have internet access, the education program is delivered in a two-tiered manner, using Lotus LearningSpace, a web-based learning management system:
- Tier 1 – Self-paced Study (for participants without high-speed web access)
- Training comprises content modules delivered via the Web. Participants log in to a web site, navigate through the material in the prescribed order and take related quizzes on the material to demonstrate their understanding.
- Tier 2 – Synchronous Online Sessions (for participants with high-speed web access)

Each participant or group of participants "attends" a live session conducted via the Web. The instructor teaches from a central project office and leads the group through a demonstration of the B-LPS system using animated graphics and videos. A period for questions and discussion follows. Participants log in to the same web site as in the first tier and view the graphics and video on their computers. The instructor and trainees telephone a toll-free conference call number to participate in the audio component of the session.

These delivery methods will allow the curriculum to be used effectively immediately, regardless of computer availability, while allowing the program to expand as computer and Web resources at individual sites expand. Furthermore, multiple delivery methods will allow home- and office-based, self-paced learning to complement more traditional training approaches.

Broader Blended Learning

Even as clinical practice is dynamic and constant, so is the ever-growing scope of color coding in health care. The growing interest in additional areas where color coding can be applied has drawn further support from the grant's federal funding agency to address issues such as disaster response, bio-terrorism and chemical warfare. Educational content on these topics will be updated and adapted for delivery via the dukehealth.org web site, further extending the blended approach to color coding.

Medical error is an urgent issue in health care and the problem in pediatrics is particularly acute. And color coding makes a valuable contribution to medical error reduction. At Duke, the blended approach to e-learning offers the best method for delivering engaging content most efficiently and effectively.

Reusable Learning Objects: Critique & Future Directions

First Author: Steven Shaw, Ph.D.
Second Author: Sarah Sniderman, M.A.

Introduction

The concept of reusable learning objects is at the heart of current thinking in the field of elearning (Wagner, 2002; Wiley, 2002). The concept is simple: instructional content is broken down into small pieces of content which can be re-used, re-purposed and shared across courses and potentially across organizations. In academic research, the concept has been alive for more than a decade, often linked to a vision of shared object libraries that might leverage the creation of low-cost, high quality instruction (cf. The MERLOT project). In the corporate world, RLOs are viewed as a solution to problems associated with on-going maintenance of training programs in dynamic fields, and the periodic changes in IT that require redeployment of existing courses on new platforms every few years.

Despite the promise of RLOs, actual examples of successful deployment of RLO technology are thin on the ground. There are several explanations for this, some related directly to RLOs and existing, associated standards, and some related to wider technology -related and organizational issues.

In this paper we first provide an overview of these issues and then explore the future of RLOs based on emerging technology, new design methodologies and new approaches to organization.

General technology issues

The limited impact of RLO technology can be attributed, in part, to several more general technological barriers. A basic one is the cost and relative inflexibility of existing, large scale Learning Management Systems (LMS). In large organizations, these systems are often implicated in complex implementations that cost seven figures, while the implementation projects are also "owned" by IT services. Once implemented, established structures are "locked in" to a large extent, due to the costs and effort required by the initial implementation, and possibly also due to ownership by IT. For small organizations, the cost of LCMS systems is prohibitive, and the systems are not scalable, particularly given the pervasive use of "per seat" licensing agreements.

Existing technology standards pose their own problems, as well, at least for some organizations that may have their own specific requirements. For example, SCORM compliance basically dictates that curricula managed by the system are lockstep; no branching is permitted. Hence, existing commercial LMS systems do not generally support branching, and various workarounds are required (such as handling branching within an integrated Learning Content Management System or LCMS) for this, and other, limitations.

Current generations of LCMS and authoring tools have their limitations, also (Chapman & Hall, 2002; Spohrer, Sumner & Shum 1998). Typically, authoring and LCMS systems are client-based. They support a classical Gutenburg publishing paradigm, requiring the services of individuals with specialized technical skills and knowledge, and a workflow model that involves role differentiation and a multi-step publishing process: there are subject experts, instructional designers, courseware authors, media producers, graphic designers; there are scripts, storyboards, media assets, assembled courseware. This model works well given certain assumptions, in particular the assumption that training program content has a reasonable shelf life. The reality in most modern organizations is that knowledge is dynamic, and training content is under constant revision. In the current world, best practices, business strategies, business rules, procedures, policies, products and services are all found to be in a more or less constant state of flux.

The Gutenburg paradigm is not responsive to this reality, even in its contemporary digital incarnation. It is unlikely that RLO approaches, operationalized within technology that reflects the Gutenburg paradigm, can meet the challenge. Why should organizations invest in the kinds of analysis and process changes required of an RLO approach, not to mention the supporting technology, when the larger paradigm within which the RLO concept is currently embedded poses a significant barrier to timely maintenance of training systems?

The RLO approach is one of the finer points of elearning strategy and technology. Basic barriers to entry into systematic elearning strategies such as those described in this section have necessarily impeded the development of methodologies, technologies and standards related to RLOs.

Conceptual and methodological issues related to RLOs

Despite a proliferation of technical standards and standards bodies -- SCORM, IMS, AICC, ADL, Dublin Core, ARIADNE, IEEE LTSC, to name just some -- there are really no accepted nontechnical standards concerning the actual nature and grain-size of learning objects from a content perspective. Typically, standards allow anything from a low-level subtopic all the way to an entire curriculum to constitute a learning object. Selection of appropriate grain-size is a nontrivial decision within a RLO strategy. Once having made that decision, description of RLOs so that they can be searched out within a large repository is also nontrivial. The problem is exactly the one we have all experienced through our frustration with Internet searches. Existing meta-data standards are technical in nature: they assure interoperability and reusability of objects. They do not point the way to indexing schemes that will ensure learning objects are locatable.

At least part of the problem is related to lack of content models for specific domains or fields. Only the aviation industry has a well-established, well-validated content model that has served over time as the basis for structuring information and documents. Developing a content model or taxonomy that can serve to guide organization and indexing of learning objects is a significant task, and not one that is a part of traditional instructional systems design methodology. It is in fact a true, very significant knowledge engineering task. Some work in the direction of extending instructional design methodology in the direction of learning object approaches exists. Perhaps the most commonly cited is Cisco Systems' Reusable Learning Object Strategy. But these extensions really only provide general guidance while pointing at the harder knowledge engineering tasks.

To make matters worse, even once a set of guidelines for describing contents in meta-data have been worked out there remain significant problems. First, authors of learning objects must be able to apply the guidelines in a consistent manner. This requires training, just as librarians require training and practice to apply the Dewey Decimal system consistently. Secondly, filling out content and authoring related meta-data fields may be a time-consuming task, if the content model is relatively sophisticated. Finally, and perhaps most significantly, in general, any conventional indexing scheme, even if implemented in meta-data, has real limitations. Full text indexing of learning objects will lack discrimination. Mechanical indexing, on the other hand, cannot cope with the fact that the same subject may be referred to by multiple names (the "synonym problem"), nor that the same name may refer to multiple subjects (the "homonym problem"). Using current approaches, success at finding the right learning objects in a large repository might be as likely as finding the exact information you want on the internet via your favourite search engine.

A final conceptual problem relates to the notion of context (Augier, Shariqu & Vendolo, 2001). Current theories of learning and instruction emphasize the situated nature of learning, and the requirement to contextualize information presented to the learner if one is to expect long-term retention, understanding and transfer of training to operational environments. Small-grained learning objects would typically be void of context and would have to be recontextualized for specific purposed and audiences. Outside of more abstract domains such as, for example, statistics, it is possible that the requirement for context will work against the leverage of a learning object approach by limiting sharing and reusability. There is some academic work in the direction of formalizing and describing context, but its applicability and practical value has hardly been demonstrated.

To summarize, it hardly obvious what, exactly, learning objects should comprise, and existing instructional design methodologies are not based firmly on an object-oriented approach. The importance of context poses a complication for learning contents organization on any finer-grained object basis. Content models are required but are in short supply. And new methodologies for indexing are definitely needed if we are ever to locate relevant learning objects once they have been created and stored. Finally, the importance of context poses a complication for any organizational scheme for learning content predicated on the basis of finer-grained objects.

Organizational Issues

RLOs are ultimately, and logically, linked to other applications beyond training, including corporate document and image management systems, knowledge management systems, and human resource information management systems. In a truly comprehensive, rational and strategic approach to managing intellectual capital within an organization, small units of content maintained in a repository would be shared and reused across different applications. A standard operating procedure, for example, would appear in different places -- memos, manuals and training materials, say -- but would be stored in one instance and presented within these different documents as they are created and formatted dynamically. Such a vision complicates IT considerations, standards adoption, information architecture design and obviously raises barriers of an organizational nature. How exactly is an overall organizational information architecture to be designed and implemented? How is the required level of co-ordination and the required depth of analysis to be achieved?

And how, from a technological standpoint, is this vision to be accomplished? Document mark-up languages such as SGML and XML hold the key to multi-purposing of content. Many existing LMS and LCMS systems support XML, to the degree that they can export data in an XML format. However, reuse across different document types requires a further degree of sophistication in document formatting that is not part of the current functionality of LMS or LCMS systems. Extensible Style Sheets (XSLs) provide the required functionality, but some considerable technical expertise is required to design, implement and maintain these within an organization.

A typical problem in large organizations, one which only partially captures the complexity alluded to above, concerns the integration of LMS and LCMS systems with human resources information management (HRIS) systems. Many larger organizations maintain competency databases within the HR function. These databases contain models which describe, in varying degrees of detail, the knowledge, skills and attributes (KSAs) which are required of different jobs, roles or tasks, and they document the KSAs possessed by any individual employee at a given point in time. Competency models may be tied to performance review systems, employee professional development programs, and to decisions and planning related to hiring, succession and promotion (McLagan, 1997; Mirabile, 1997; Sanchez, 2000).

LMS systems manage training: they register individuals in training programs, track their progress and performance throughout different courses and report related information concerning individuals or groups. Logically, if a competency approach is in place, it is desirable to integrate LMS and HRIS systems. Completion of courses by an individual, registered by the LMS should lead to updates to the competency model describing that individual.

But how exactly will this work? There is probably not a one-to-one mapping of courses to competencies to begin with, and stated course objectives may be more, or less, precise. Take a more sophisticated situation where we envisage courses assembled from learning objects and customized to meet individual requirements. Could there be a one-to-one mapping in this case. Not very likely. First, there is the grain size issue. Does one learning object correspond to one item with the KSAs? Are the learning objects described in a corresponding way? How does this work? Can the competency model replace a content model? Can you build courses out of learning objects designed to correspond with the competency model? Is this a logical and a practicable thing to do? And competency models typically describe the specific behaviours that would demonstrate generic KSAs within particular roles or domains: a theatre director and an engineering project lead may both exhibit leadership qualities, or conflict resolution skills, but it won't look the same. So are we once again confronted with the problem of contextualization of learning objects? Finally, competency models are not all cut from the same cloth. Some define competencies in terms of attributes of individuals (the KSAs) while others define them in terms of tasks or results or outputs. Some models focus only on what differentiates superior performers. Models also differ in regard to their level of detail. This variety complicates the prospect of any coordination between a content model developed by an industry, domain or sector and a given organization's competency model. Clearly, the relationship of learning objects and LMS reports to competency databases is not obvious. In this example we have not even stepped outside the limits of the HR/Training domain and already significant problems are apparent.

The future of RLOs

Despite the problems identified above, RLOs seem to be the future. Emerging technologies offer some hope for resolving key impediments to successful implementation of RLOs. New trends in organizations promise to facilitate integration of learning object strategies within more encompassing information and knowledge management initiatives. Given that such wider initiatives are undertaken at the highest level of strategic planning in organizations, they may in turn provide more momentum and opportunity for learning object initiatives on the training and human resource fronts, where traditionally spending has been viewed more strictly and simply from a perspective of cost. In the future the imperatives of regulatory bodies may also play some role in driving the development of the necessary content models on an industry or sector-wide basis, as has happened in part in the aviation industry.

On the technology front, there are several promising developments. First, XML-related technology and standards are maturing. Future LCMS technology will take greater advantage of tools such as XSLs to facilitate the integration of LCMS with other knowledge and information management tools within organizations.

Second, primary barriers to entering into elearning will continue to fall. The next generation of LCMS tools will be browser-based (see Rocket KM from EED Knowledgeware Corporation as an early-to-market example of this next generation). Anyone within an organization may be empowered, or tasked, to create, validate or edit learning objects, through their desktop browser. A new post-Gutenburg paradigm of information and knowledge dissemination can thereby be implemented. Up-to-date knowledge and information can be moved to the frontlines of organizations in a timely manner, allowing a fuller realization of the potential benefits of learning object approaches. Plain vanilla (no plug-ins required), browser-based LCMSs will also offer an additional advantage: there will be minimal requirement for IT input to implement the tools, thus limiting IT ownership and control of elearning, knowledge transfer, and learning object initiatives.

Newer LCMS and LMS technologies are also being priced more competitively, and using pricing strategies that are more scalable: for example, pricing may be based on licenses tied to the number of servers distributing content, rather than the number of seats. Economic barriers to entry into elearning in general for smaller organizations are falling.

Methodologies for design based on the learning object paradigm are still under development. Future developments may see the explicit use of heavy-duty knowledge engineering techniques to develop and validate content models. Integration of elearning and electronic performance support with wider, strategic, organizational KM and information management initiatives will provide the justification for the depth of analysis and the effort required to accomplish this task.

The issue of context its role in RLOs is a thorny one. Indexing learning objects to indicate contexts where they are applicable or reusable is likely a nonstarter for some domains, though in some instances reusability may not be a key issue for these domains. However, an analogous problem is encountered in case-based reasoning (CBR), an AI approach which has produced a significant body of work, and which met with success in certain domains (Aamodt & Plaza, 1994; Kolodner, 1993). The basic idea behind CBR is that most high-level cognition (e.g., problem-solving, design tasks) does not proceed from first principles. Rather we retrieve cases concerning similar situations and their solutions from memory (or external resources) and adapt components of the solutions to the current case. Cases must be broken down into components; decisions must be made about the grain-size of cases, and; case components must be indexed for situations in which they may fail or be successfully adapted. The parallel to the problems of defining RLOs and indexing them for applicable contexts seems quite good, at least on the surface, and some of the lessons derived from CBR research may be generalizable to the RLO context.

Finally, the general problem of indexing learning objects from a contents perspective begs a solution. The solution may come from the new methodology conveyed in topic maps. Topic maps provide an approach that marries the best of several worlds, including those of traditional indexing, library science and knowledge representation, with advanced techniques of linking and addressing. Topic maps create a semantic web. The map captures the subjects of which resources speak, and the relationships between subjects, in a way that is implementation-independent. It conveys knowledge about resources through a superimposed layer, or map, of the resources. The map furnishes directed graphs which indicate meaningful relations among resources.

The topic map paradigm has been under development since 1993, when it was first articulated in a working document from the Davenport Group. The paradigm was more fully developed thereafter in the context of the GCA Research Institute (now known as IDEAlliance), in an activity called Conventions for the Application of HyTime. Early in 2000, the topic map paradigm was fully formalized for the first time as an ISO International Standard, ISO/IEC 13250:2000. Since then, TopicMaps.Org was founded in order to develop the applicability of the paradigm to the World Wide Web, and to realize its enormous potential to improve the retrieval and management of information.

Conclusion

There is considerable work to be accomplished on all fronts -- design methodology, organizational approaches to learning and knowledge management, collaboration within sectors and industries on content model development and standards, and technology -- before the potential of learning objects and RLOs will come to fruition. Despite the obstacles, there are trends apparent in all these areas that offer promise, not least of all on the technological side.

The Design of Interactive Applets for Mathematics Education

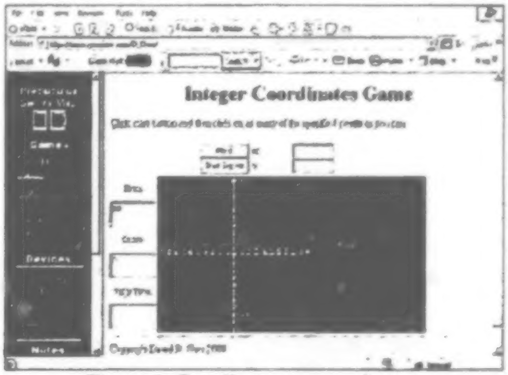
David B. Sher
Mat/Sta/CMP Dept.
Nassau Community College
1 Education Dr.
Garden City NY 11530
sherd@ncc.edu

This paper discusses the design of interactive applets for mathematics education. These applets were designed to use the Java AWT package (the graphical user interaction package that was part of the original Java distribution) so that they should run on the maximal possible set of browsers. The web site for these applets is http://www.calclet.com. Several challenges of designing applets for education are:

- Instructions for applets so they can be used.
- Layout of applet elements for reliability and ease of use.
- Interactive graph paper.
- Data sets from potentially unreliable internet sources.
- Using applets in a computerized classroom.

Web Page Instructions

I have found two methods for designing web pages containing applets. One method is to make using the applets fairly simple so the instructions can take only one or two sentences. Such applets may have only one button and one task to perform. For example in the coordinates game, figure 1, the user has only one button to press which starts the game and only one text field to modify, total time (accommodating students with special needs). Playing the game is quite simple too. Thus students can use an applet like this quite quickly after being introduced to it.



Integer Coordinates Game

Figure 1: Coordinates game web page

More complex and sophisticated applets require more sophisticated instructions. For example in the stock modeler web page, figure 2, the user must select a stock symbol, decide which statistic of the stock he wishes to use, and then write a modeling function. There are buttons, text fields and lists that are used to perform these functions.

BEST COPY AVAILABLE

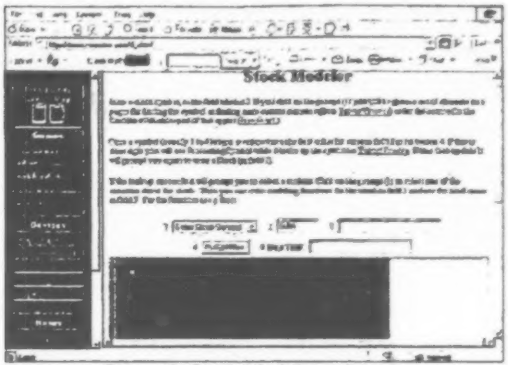


Figure 2: Stock Modeler web page

Numbering the various buttons, lists, and fields of the applet simplifies and clarifies the explanation of how to use it.

Detailed notes will be available for the applets once the package is complete.

Applet Layout

One of the most annoying aspects of designing java applets is the propensity of applets to leave out any fields or buttons that the layout manager can't fit in. There are several tricks needed to layout an applet so that the controls will not disappear and will be easy to use.

- Grid layouts make every item the same size. A large item is in a grid then every item is allocated the same space. This leads to overly large panels that then are often not displayed in the applet. Grid layouts should be used at a minimum.
- Controls for the applet can be placed around the applet on the left right or bottom of the applet. The most salient controls should be atop the applet but less important controls may be placed on the bottom. For example, in the slope drill applet, figure 3, the user selects two points and then must determine the slope. The user has the option to change the maximum value of X or Y on the graph. However, this should be used rarely to illustrate certain specific mathematical points. So, the fields and buttons to control the maximum values for X and Y are placed on the bottom of the applet.

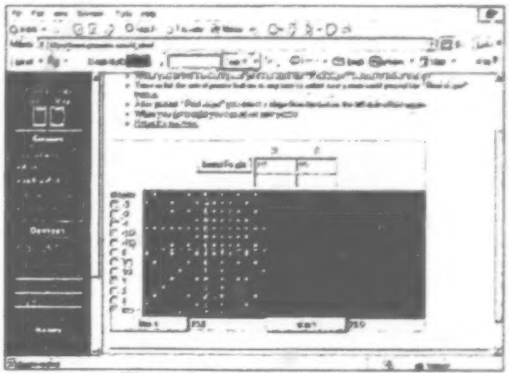

Figure 3: Slope drill web page

BEST COPY AVAILABLE

Interactive Graph Paper

Figure 1, figure 2, and figure 3 use a package of animated graph paper. This paper can change the range of the X and Y axis. Points can be placed on it or lines or more complex functions. When the user clicks on the paper, the program can determine where the user clicked on it and decide what to do about it. The slope drill, figure 3, uses all of these features. The Max X and Max Y fields allow you to change the ranges displayed. The display of two different kinds of points is shown in the figure. The user selected the blue point and the applet is waiting for one of the yellow points to be selected.

Internet Data Sets

The stock modeler, figure 2, and the economy modeler get data from internet sources. This presents two significant problems. One is that applets can only contact web sites on their own server. This was avoided by using a CGI web page on the server to access the web sites for the applet.

Another problem is that these applets are dependent on other web sites for their data. The stock modeler is dependent on Yahoo finance and the economy modeler uses the IMF. If these sites stop supplying the data or change the format the applets will be unable to access this data (stock prices or economic data). We are attempting to solve this problem by finding multiple data sources.

Computerized Classroom

While these applets can be used for distance learning, they were designed for use in a computerized classroom. These issues need to be addressed in this environment:

- Some students are uncomfortable with new teaching styles. These students often are good students, who were successful in previous math courses. My experience was that many of these students came to enjoy the games and drills available when they were successful. Usually a bit of personal hand holding was necessary to get these students started.
- Some students have serious problems using computers, due to psychological reactions or physical challenges. Every timed applet has a total time field, see figure 1. Changing the number in this field can allow these students extra time.

In the computerized classroom students often help each other navigate the web and use the applets. This collaboration among the students actually improves their performance in class. The modeling applets are designed to be used by groups of students collaboratively in semester long projects.

Summary

A package of applets has been designed for mathematics education. Several techniques for designing educational material in java are presented here. This paper focuses particularly on presentation of instructions, applet layout, use of the interactive graph paper, accessing data over the internet and using these applets in a computerized classroom. This package has been successfully used in a typical precalculus class at Nassau Community College.

An Evaluative Study of a Distance Education Degree Program Using Focus Groups

Ching-Chun Shih (ccshih@iastate.edu)
Dan Dobill (ddobill@iastate.edu)
Ann Thompson (eat@iastate.edu)
Iowa State University

Abstract: The purpose of the three focus groups with the seven advisory panel members and 16 students was to evaluate the program in general so as to improve and strengthen the program. The participants of the focus groups identified the important or effective aspects of this program as well as its convenience, relevance, coverage of quality information, accelerated learning potential, structured lesson schedule, and the use of CD-ROM. They suggested the instructors to grade the assignments in a timely fashion. The participants thought the students of this program had fewer personal interactions with instructors or major professors than those in a traditional program. This program was as challenging as they expected, but they did not expect the intensity of the time commitment. Based on the results of this study, actions of improvement have been implemented.

Introduction

The Master of Science in Agronomy Distance Education Program of Iowa State University (ISU) has provided interactive multimedia courses delivered through the Internet and CD-ROM. This program uses three types of instructional technologies: course content, electronic communications, and electronic posting (Nguyen & Kira, 2000). The course integrates content material on CD-ROM/WWW with the interactive tools of WebCT (WebCT, 2002) on an ISU server. For electronic communications and posting, WebCT (know as the Student Notebook System in the program) has been used to allow students to interact electronically with their instructors and classmates by utilizing a course calendar, a discussion board, student homepages, an assignment area, student email addresses, and individual student records.

This program provides an opportunity for agronomic professionals working in industry and the government to obtain an advanced degree while continuing their employment. It began with an enrollment of 15 agronomic professionals in the fall of 1998. Currently, there are 128 students enrolled. By the summer of 2002, seven students completed and earned their degree. The students have to complete 12 courses, a one-credit workshop, and a three-credit creative component, which totals 30 semester credits to complete the degree (Iowa State University, 2002).

The program has conducted a series of formative evaluations to learn students' experiences in the program and to obtain an understanding and knowledge about Internet-based learning and teaching so as to improve and strengthen the program. The most current formative evaluation activities were the three focus group interviews in 2001. This paper presents the study purpose and objectives, methodology, results, conclusions, recommendations, and action for improvement based on the results of the focus groups.

Purpose and Objectives

The purpose of the three focus groups was to evaluate the program in general so as to improve and strengthen the program. Specifically, the objectives were to identify the important or effective aspects of the program, obtain suggestions for enhancing the curriculum, understand how this program was perceived as compared to a traditional one, and recognize the expectations of the advisory panel and students for the program.

Methodology

This study used the technique of focus groups to collect data. Being a form of qualitative research, the focus groups are group interviews, which mainly rely on the interactions among the participants to produce insights on the topics asked by the researchers or moderators (Morgan, 1997). Typically, the researchers encourage participants to talk to each other, ask questions, and comment on each other's experiences and points of view, which usually causes the participants to become an audience for each other (Kitzinger and Barbour, 1999).

The first focus group was conducted with the seven advisory panel members of the program while they attended the annual advisory panel meeting in March of 2001. The advisory panel members were the agronomic representatives from industry, government, academia, and student body. Only one of the seven advisory panel members was a student representative. The participants of the other two focus groups were the 16 students attending the workshop course on campus in July of 2001. There were seven students in one group and nine in the other. With the consent of the participants, the three focus groups were audio taped. Based on the analysis of the tape transcripts and the researchers' notes, the results of the three focus groups are presented as follows.

Results

Important or Effective Aspects of the Program

The participants of the three focus groups were asked to discuss the important or effective aspects of this program based on their experiences and observations. In general, they noted that the important or effective aspects of this program were its relevance, coverage of quality information, accelerated learning, convenience, flexibility, application emphasis, fixed lesson schedule, and the use of CD-ROM in the program.

The advisory panel members believed that this program provided relevant materials to students who were professionals in their fields. The student representative of the advisory panel revealed that courses offered by this program "*stimulated [students] to think creatively about the material much more than on-campus students would.*" In addition, one panel member was impressed with the various topics and quality information covered in the courses, as well as the additional references linked in the lessons. Another panel member added, "*just to have [the] access to those references, that's an incredible part of the course.*" One panel member anticipated this program would provide accelerated learning to the students because they could work at their own convenience, get a lot more done in a short time frame by being able to access the references on-line and save the commuting time. In addition, the student representative was impressed that the faculty and the course development team were able to finish developing the courses and deliver them on time. He further added that with the quality of the courses, he "*was surprised that it (this program) is not winning awards.*"

In the two student focus groups, one student admitted that convenience was a key reason for him to be involved in the program. Another two students were positive on the convenience of "not having to devote all [their] time getting to and from." Three students agreed that the option to work on the CD-ROM was a "*lifesaver.*" They also liked the convenience of using the CD-ROM and one student added, "*It is much better than being on-line... you don't have to be connected all the time.*" Another student further explained, "*Because I travel a lot, I can just pop that CD into [my] laptop and go through a whole lesson on a plane and also submit the assignments over the Internet. It is so convenient!*"

One student liked the materials he learned in the program because they were "*more in the field applicable level rather than [in] the theoretical aspect.*" In addition, another student enjoyed getting different perspectives from the diverse discussion groups. The time frame of week-by-week lesson was a very good format according to a student. He noted, "*it is structured so that you discipline yourself to get through all of the material in that lesson instead of just moving on.*" Moreover, a third student summed the effective aspects of the program by saying, "*The information I guess is affordable; it's available; it's applicable; and it is a quality course. The folks that go through this [program]...are going to be in a competitive advantage as they move through their career.*"

Suggestions for Enhancing the Curriculum

Not only did the focus group participants share their opinions about the important aspects of the program, but they also discussed their concerns about the program and provided suggestions on how to enhance the curriculum. The advisory panel suggested the program add business related courses and increase the social interaction aspect of student learning. They agreed that there was a need for the program to provide business related courses, such as business management, communications, and agriculture economics. Several panel members noted the lack of social interaction among the student peers was one limitation of the program. However, the student representative in the advisory panel stressed that he did have good opportunities to interact and communicate with his peers via emails and structured discussion topics. But he also "*enjoyed a great deal*" the face-to-face conversation he had with the students at the summer workshop. He concluded that it all depended on how to look at this aspect by saying, "*Wouldn't it be nice if we had to do this a couple times a year, but then immediately you would...[think] it's fine for us that are all within Iowa and neighboring states, but for them (people live far away) it is just trade offs...I think that kind of depends.*"

The biggest concern of the two student focus groups was with the instructors' feedback. Most of the students in the other two focus groups expressed their frustration with not getting their assignments graded in a timely manner. A student stated, "*Most of the folks (students) I have talked to have problems getting assignments, grades, and things like that back.*" Another student added, "*that is very hard to get...you don't know what your progress is.*" A third student further argued, "*I guess if we are expected to have assignments done every Tuesday morning, why shouldn't we expect the same out of the professors?*"

Several students suggested that instructors reference the textbooks in the CD-ROM lessons. One student noted, "*They (instructors) had a lot of stuff in there (CD lessons)...[they] just didn't reference back to it at all...I mean you just didn't know where you were looking.*" In addition, several students thought it would be helpful if they could submit their assignments as attachments through WebCT especially for the courses that use math symbols. Also, several students would like to use more tools in WebCT, such as e-mail, and chat room functions. Furthermore, one student suggested using MSN Instant Messenger in the program. In that way, "*you can chat while you are doing homework...you know when somebody else is on-line and it gives you a prompt,*" according to this student. Moreover, several students had concerns about the advisor system. Another student suggested assigning advisors right after students start their program and they can easily switch later. "*Just so you have someone consulting with you,*" this student explained further.

In addition, many students suggested the program make hard copies or audiotapes of the lesson contents as an option for students to purchase. Two students noted that using the hard copies were easier to make notes, study for tests, and locate the concepts they just learned compared to the WWW/CD-ROM format.

As Compared to a Traditional Program

The participants were asked to discuss how they perceived this program as compared to a traditional degree program. The panel members of the first focus group believed it was an important and necessary way to have this program and it was "*a very natural progression of how education should work.*" One member emphasized that this program "*was an additional way, and it has to be an effective way to meet a critical need.*"

Several students in the other two groups noticed the differences in interactions or self-discipline in research. They believed that they had fewer personal interactions with instructors or major professors than those in a traditional program. One student suggested, "*Maybe we need actual physical interaction, person-on-person, once a year or twice a year... the eyes, the hair, and the way you represent yourself. I want to see Dennis Todey (one of the instructors) in person.*" Furthermore, several students expressed that they would have taken classes on campus if their situations permitted. However, one student admitted that this program was better than a traditional one to him by asserting, "*If this wasn't a distance program, we wouldn't be going after our masters.*" He then continued saying, "*It is a very favorable way you are doing it... the drawback... is you don't have that long one-on-one interaction as if you would [learn from a traditional program].*" In addition, several students revealed that in this program, they had fewer opportunities to talk to their major professors about research than those in a traditional program.

Expectations for the Program

Most of the panel members' expectations for the program were related to the program quality. One member noted that at the beginning he was afraid that this program would produce a "cheap degree" and he was glad that this program did not turn out that way. Another member added, "*I think that my expectations continue to be this: How do we meet all commitments within [our] students? To ensure quality education, I think the university has an obligation to provide [the learning opportunities] to any learning individual whether on campus or not.*"

The student representative in the advisory panel stated that he "*enrolled in the program to not become a research agronomist, but to become more familiar.*" As a student, he originally expected the program "*to be less challenging than it is and to take up a little less time than it does.*" However, he was glad that this is not the case. He stressed this by saying, "*I think a program like this can be open to criticism of not being as rigorous as an on-*

campus program, so I think we need to constantly defend against that even if we error on the other side, which we have. And I wouldn't want the bar to be lowered at all in either of those areas..."

Several students in the other two focus groups expected this program to be as challenging and hard as it was when they entered the program. One student said, "***I think the difficulty level is good. I expected it to be challenging because it is not something that should be too easy or just any other Joe can come into it and get it.*** " Another student liked the information covered in the courses, which was more advanced than he thought it would be. He then continued stating, "***I don't think anybody in this room can argue that the information is not solid.***" A third student thought he learned a little more than he needed to know as an agronomist in this program, which gave him "***a little bit more credibility to people that he was talking to.***" On the other hand, several students also noticed that they did not have enough time for their families. One student said, "***The aspect we have been leaving out of here is family... not enough time for my kids. I carry my book to a ballgame.***" The students then suggested having a few students who had been in the program for a complete year to talk to new students at the orientation about their experiences and how to manage their time between family and work.

Conclusions, Recommendations, and Actions of Improvement

In conclusion, the program advisory panel and students were impressed and satisfied with the quality of the program. The participants of the three focus groups identified the important or effective aspects of this program as its convenience, user friendliness, relevance, coverage of quality information, accelerated learning, structured lesson schedule, and the use of CD-ROM in the program. The advisory panel thought that students in the program might lack social interaction among their peers whereas the students revealed their biggest concern was with the late grading or feedback they received from the instructors. The students also would like to see instructors reference the textbooks in the lessons and be able to purchase the hard copies of the course contents, do keyword searches among the courses, as well as attach files, use email, and chat room functions through WebCT. As compared to the students in a traditional program, the students believed they had fewer personal interactions with their instructors or major professors. The advisory panel was pleased to see that this program did not turn out to be a watered-down degree program as they were concerned with initially. The students thought this program was as challenging as they expected, but they did not expect the intensity of the time commitment.

The recommendations were that the program should continue providing quality courses, increase the "personal touch" among the instructors and students, as well as provide timely feedback to the students. Taken into account by the program, these recommendations have been used to improve and strengthen the program. For example, the actions of improvement included: (1) Several instructors added video clips to introduce their courses so as to increase a personal flavor in the class. (2) The Fall 2002 new student orientation was held on campus at the same time when the workshop course was offered on campus in July of 2002. A social and learning opportunity was provided for the new students to interact with the students attending the workshop. (3) The program director developed a grading policy agreement with the instructors of the program to grade, post scores, and provide feedback in a timely manner regarding assessment of student work. The results of the later course evaluations proved this effort. (4) The program created pdf format files for the CD lessons, which is an easier print solution and allow for key word searches.

Abstract: Today, the use of the multimedia to teach topics is growing at a rapid pace. However, many questions concerning its educational effectiveness still exist. What does well-designed multimedia actually look like? and, How can teachers best incorporate it into their own curriculum? are examples of such questions. The primary goal of this study was to assess the instructional value of a multimedia product through its integration it into the curriculum of a traditional undergraduate course in anthropology. As a by-product, the data also offers possible answers for these questions.

Introduction

In the fall of 1996, the Arkansas Archeological Survey and the Department of Foreign Languages at the University of Arkansas, Fayetteville were awarded a $180,000 National Endowment for the Humanities (NEH) grant to develop educational software for studying Native American and European encounters in the Mississippi Valley. This project, called First Encounters, was one of only twelve proposals funded out of more than 300 submissions in the first year of the NEH Teaching with Technology Initiative. The goals of this NEH initiative were to encourage creation of content-rich, computer-based materials for teaching history, literature, and languages; to create a nationwide forum for humanities education on the Internet; and to provide teacher training for the use of these programs. The paragraphs that follow describe how First Encounters was designed and then evaluated through its implementation in a traditionally taught course.

Learning Objectives, Theoretical Underpinnings and Instructional Design Strategies

A primary goal of the First Encounters project was to help students answer the question: How does one derive from the archeological and historical record an understanding of what happened in the past? Therefore, the First Encounters CD-ROM was designed purposefully to engage students in an active investigation of many aspects of Native American and European encounters via original historical sources such as texts, maps, artworks, and archeological finds.

The Lower Mississippi Valley was chosen as the area of study because of the region's great range of cultural encounters, involving numerous British, French, Spanish, African, and Native American groups. These differing cultural perspectives between groups were used to provide a framework for students to analyze the "facts" recorded in written and pictorial documents. Since French and Spanish explorers wrote many of the original documents, language-learning tracks were also developed, making the software useful for multiple subject "teaching across the curriculum."

The English language track leads students through a detailed presentation of historical and anthropological materials that describe the encounters between Native American communities and the French, Spanish, and British explorers, traders, missionaries, and colonists who entered the Mississippi Valley during the sixteenth through eighteenth centuries. Subject modules include Two Worlds, First Encounters, Views of the Land, Exchanges, Interactions, and Legacies. The French and Spanish modules each provide four topical modules designed for enhancing foreign language skills while studying Native American and European encounters within the English track.

First Encounters was designed on Kathy Kozel's (1996) Interactive Experience Model (IEM) to provide a format for active learning across the curriculum in social studies, foreign language, anthropology, history, and geography classes at middle school, high school, and college levels. IEM may be described as an instructional design method that focuses on active learning and user engagement and is recursive in nature. Successful user engagement is defined as achieving flow state as outlined by Mihaly Cikszenmihalyi (Kozel, 1996). Briefly, flow state "is a state in which an individual has no conscious awareness of time passing; it is a state of complete engagement" (p. 62).

Following this instructional design model, hundreds of interactive screens were created to allow the students to arrive at their own interpretations by applying anthropological concepts to the raw materials of history. Further, the interactive screens engaged students in the process of learning first-hand the methods of historical and anthropological analysis by offering dozens of exercises, tutorials, quizzes, and essay prompts with step-by-step instructions.

Research Design

In order to evaluate the quality of the First Encounters CD-ROM when production was completed, Dr. George Sabo integrated the CD-ROM into an existing undergraduate course, ANTH: 4813: Ethnographic Approaches to the Past, as a learning tool. The course was taught in a seminar format that included: the CD-ROM as a central feature, traditional lectures, a WebCT discussion forum, and three textbooks. These books were: The Indians' New South by James Axtell (1997), The Old World and the New by John Elliott (1990) and The Emperor's Mirror: Understanding Cultures through Primary Sources by Russell Barber and Frances Berdan (1998). All of the reading assignments, project due dates, and other significant class schedule information was posted in the WebCT forum. In addition, students were instructed to post their essay responses in the forum. The primary objective of the course was to teach students how to critically evaluate primary source materials and extract useful information from those materials. In short, the main goal of this class was to instruct students how to do anthropological research using historical source materials.

Once again, the primary goal of this study was to assess the instructional value of a multimedia product in an authentic context within a unique case orientation. As a by-product, the data also offers possible answers to the two questions posed earlier. This study employed two types of document analysis in order to: evaluate learning outcomes, examine user patterns, and probe student perceptions and attitudes. The CD-ROM contained essay assignments that were collected from the students during the course term and qualitatively analyzed by Dr. Ann Shortridge to evaluate the quality of instructional design method used to present the materials via learning outcomes. In addition, at the end of the course students were asked write summative essays that were also qualitatively analyzed by Dr. Shortridge to: examine user patterns, and explore student attitudes and perceptions about their learning experience. A high middle and low achieving essay of each type was randomly selected and coded for themes and patterns. Three CD-ROM contained essays (one low, middle and high achieving) and six summative essays (2 low, 2 middle and 2 high achieving) were analyzed in order to gain a representative view of all of the participants. (I.e., a cross section snap shot of the entire student population can be seen by randomly selecting members from each group.) When reading the next two sections of this paper please note that "fes" denotes a First Encounters summative essay 1, 2 and so on and L, M, H denotes low, middle and high achieving levels. The CD-ROM contained essays findings are not reflected by individual student quotes, but contained in the general summary of results concerning learning outcomes.

Features of Well-Designed Educational Multimedia

Analysis of both of the data types provided a good description of what well-designed educational multimedia looks likes. It is interactive or engaging, informative, well structured, practical and yields favorable student ratings. Analysis of the CD-ROM contained essay responses showed that students were able to use the analysis techniques included within the CD's content/software to adequately identify and describe the differing and changing worldviews of Spanish explorers and Native Americans through examination of primary source material. Therefore we can assert that the analysis techniques included within the CD's content/software contributed to successful learning outcomes. Analysis of the summative essays highlighted student perceptions of the total learning experience. Selected student comments from the summative essays are provided below in order to illustrate what aspects of the curriculum the students found most valuable.

All of the students rated their own learning experience highly. One student shared the following: The ability to critically analyze various materials is a skill that any decent anthropologist needs, and I felt that I am getting closer to that goal. I might not remember exact details about the Quapaw calumet ceremony, but I feel I could semi-competently analyze historical documents on the subject. I also learned that the written word is not the definitive source to look at when researching a particular topic. One must look at a broad range of material in order to get a clear picture…(fes3_L).

Another student elaborated: The exercises really provided us with the means to (or forced us depending on your perspective) to really work with and critically evaluate an enormous wealth of primary source material, pull useful information from those materials, and use that information in an assortment of creative ways. Beyond any fragment of a doubt, we stayed busy working with this software. On top of this, I dare say that we learned diverse techniques and considerations in a way that was uniquely executed and highly effective in the goals it was designed accomplish (fes2_M).

Yet another student commented: The CD-ROM was quite a switch from other classes I have taken, which make you memorize boring facts and expect you to regurgitate them in the form of multiple-choice tests. The CD-ROM had a wide variety of materials that was open to any interpretation, so long as I could back up my points (fes3_L).

Two thirds of the students indicated that they believed that use of the CD-ROM increased their level of engagement within a traditionally taught course. One student said: I think that the CDROM allowed for the class to keep to a schedule better, since it was divided into segments, and you had to complete the essay as soon as you were finished reading the material (fes3_L).

Another student asserted: The lessons on the CD-ROM are grouped in a very intuitive and logical manner according to meaningful categories, especially for individuals who would be unfamiliar with a great deal of the jargon associated with anthropological research. Additionally, the qualifying of the exercises into beginner, intermediate, and advanced increases the utility of the program by allowing its use by a broader demographic (fes_1M).

Students also commented on the other instructional tools used in this course. Their comments highlight how educational multimedia can be successfully integrated into traditional courses. Please note that students were not requested to comment on traditional lectures and a larger sample might yield greater insight regarding computer-based tools.

All of the students asserted that they believed that the textbooks used in this course were exciting, and beneficial. Students further elaborated that the textbooks supplied needed guidelines and background information. One student said: I found the books to be rather exciting…

Another student shared: The texts functioned well as a good segue into the real meat of this course: the First Encounters software…

Yet another student asserted: The textbooks were very beneficial as a source of background information. The books helped in the understanding of what the Europeans expected to see when they left Europe and how their view of the world was shaped by their culture (fes10_L).

In addition, many of the students expressed that the textbooks integrated well with the use of the First Encounters CD-ROM. One student stated: The authors' explanation of the reality-mediation model also proved very helpful for the eventual applications and interpretations necessary for the CD-ROM [exercises and essay assignments].

> Another student shared: I felt that you [Dr. Sabo] did just as good a job of presenting theoretical models as did Barber and Berdan. And while their work was useful, I found your explanation of models to be equally useful - perhaps even more useful since the CD combined the explanation of models with practical exercises (fes9_H).

While only a few students mentioned a specific preferences for other computer-based tools, several students affirmed the value of posting assignments and engaging in discussions in the course's WebCT forum. One student's comments about the use of WebCT as a discussion and essay publication forum was as follows:

> The CD-ROM for the course, First Encounters, was both extremely informative and practical for the purpose of our course…Speaking of the essays on the books, I would like to add that I found the discussion section on the WebCT to be extremely beneficial in writing my essays. At first, I would write my essay and compare it to what others had written. That was intimidating to say the least, since most seemed to be reiterating arguments from the books, but I decided that if I messed up, I would mess up on my own merit. The amount of essays, including their length requirement, taught me how to write more precisely. Once we started working on the CDROM, I found the essays to be extremely helpful. Many people would include points that I had missed in my readings. I regret that I wasn't able to read through everyone's essays, but I did zero in on a couple of people who carried the discussions in class. The essays gave me the confidence to show my work to other people, and that was great since I had to defend my thesis this semester. I am rather shy during class discussion…I think being among graduate students made it difficult for me express myself better, since I didn't want to come across as ignorant. This final essay will probably not help diminish that image. But I also got more confidence in being able to get into graduate school (fes3_L).

Conclusions, Implications and Future Directions

A qualitative analysis of two different types of essay documents indicated that the First Encounters CD-ROM is a valuable learning tool. Analysis of the CD-ROM: contained essays indicated that the analysis techniques included within the CD's content/software contributed to successful learning outcomes Analysis of the summative essays revealed user patterns, and student perceptions and attitudes. One hundred percent of the students rated their own learning experience highly, 66% of the students indicated that they believed that the CD-ROM increased their level of engagement within a traditionally taught course, and 33% of the students indicated that they preferred learning with technology. In addition, the students also asserted that the First Encounters CD-ROM worked well with other instructional methods such as textbooks, assignments, and other computer-based tools. Therefore, it is obvious that this case study provides evidence that course authors can design effective multimedia around active learning theories and user engagement that will contribute to successful learning outcomes. However, this study is a single case study and as such cannot be broadly generalized. The results of one case study may be insightful, but the results of a series of case studies, which examine the same topic, would be more conclusive. Further case-based evaluation of the use of First Encounters in additional university and K-12 classrooms is currently underway and will provide the opportunity for a meta-analysis of multiple case results. In addition, a blueprint for disseminating the case studies along with guidelines and lesson plans on the First Encounters web site as a teacher resource is currently being drawn up.

ENHANCING INSTRUCTIONAL DEVELOPMENT PROCESSES FOR E-LEARNING

Deborah Jones
Teaching and Learning Unit
RMIT Business Online
Melbourne, AUSTRALIA

Rod Sims
Teaching & Learning Support Unit
Deakin University
Geelong, Australia

Abstract

Many tertiary institutions in Australia provide support to develop online teaching and learning resources, an environment characterised by demands from students for quality face-to-face and distance education, staff concern over workloads, institutional budgeting constraints and an imperative to use management systems. There also remains a legitimate focus on using online learning to facilitate new learning strategies within a complex social setting. This paper presents an extended instructional design model in which the development cycle for online teaching and learning materials uses a scaffolding strategy in order to cater for learner-centred activities and to maximise scarce developer and academic resources. The model also integrates accepted phases of the instructional development process to provide guidelines for the disposition of staff and to more accurately reflect the creation of resources as learning design rather than instructional design.

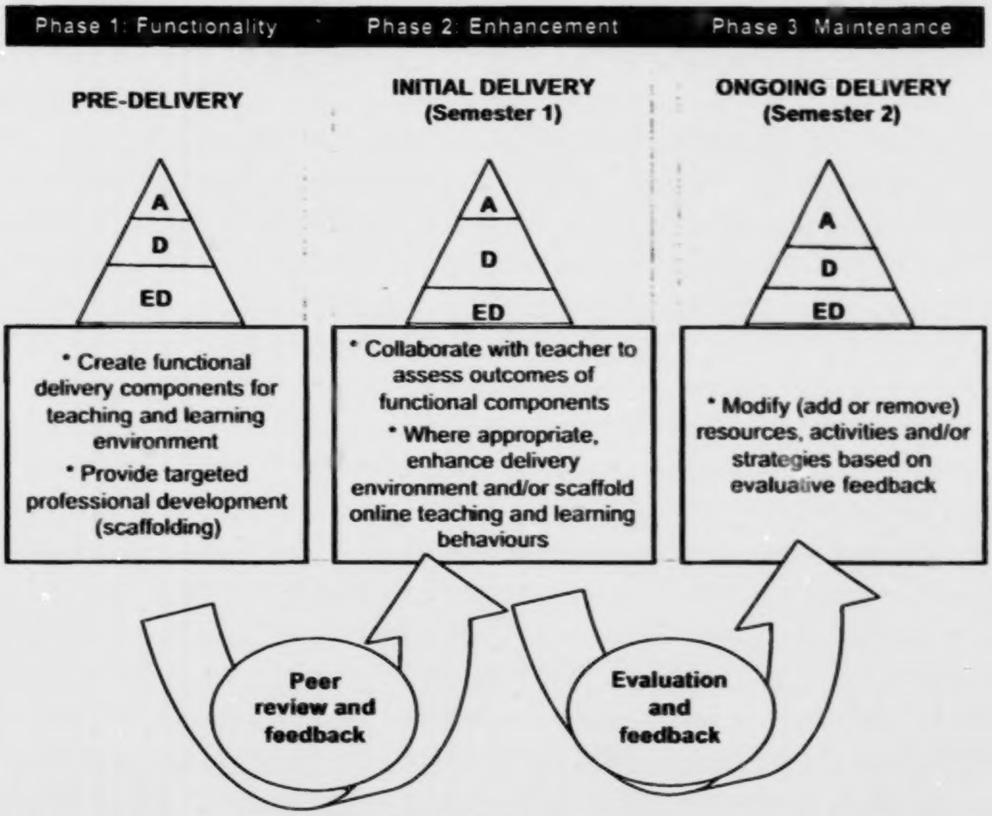
Introduction

As managers of support units in two Australian universities, we find that academic staff often have too little time or too few skills to maximise the benefits of online learning. At the same time, our institutions, like many others, are emphasising the role of enterprise-based Learning Management Systems. Within this environment, our roles involve the design and development of online teaching and learning resources within tight timeframes and institutional constraints. This short paper provides some insights into strategies that may increase production efficiency and enable ongoing maintenance of online environments. The focus of our speculations is in the context of a single Faculty, but could be expanded to the whole unit or contracted to a single unit.

A Three-Phase Design Model

Integral to this process is he notion of iterative development or successive approximations, with initial prototypes being built to *test the water* before completion of the entire course. In the first iteration learning environments are generally created to provide functional delivery with the necessary componentry for effective online teaching and learning. This can include the outputs of a preliminary needs analysis of the learning environment and resources that are *scaled to fit* the proposed teaching and learning context. However with the second and subsequent iterations, development can be enhanced with each generational change. In addition, the model is based on a team approach, bringing together the three main elements of course development in a more lateral manner. No longer is process driving the development, but the project itself (i.e. the course) is dictating the make up of the teams (a cross section of skills from educational design and production) in a much more targeted and effective manner. These teams ideally stay formed for the duration of the project, potentially over a number of semesters, with communication and collaboration between academic staff and developers a key focus.

The model therefore reinforces both the team-based approach to the design and provision of resources as well as an *iterative* development process. One of the essential aspects of the model is the specification of *baselines* in levels that correspond to these iterations – the first relating to course functional and essential components, the second to multimedia enhancement or interactivity and the third to ongoing maintenance. These iterations are identified within the strategy as three scheduled phases of development that integrate both a methodological approach to unit development, scaffolding and quality controls and assurance, as illustrated in Figure 1.



Phase 1: Functionality
Phase 2: Enhancement
Phase 3: Maintenance

* Where appropriate, enhance delivery environment and/or scaffold online teaching and learning behaviours
* Modify (add or remove) resources, activities and/or strategies based on evaluative feedback
Peer review and feedback
Evaluation and feedback

Figure 1: Three-Phase Design & Scaffolding

An important feature of this model is the distribution of resources at each iteration (A - Academic; D - Designer; ED- Educational Designer). The outcome of our continuous improvement paradigm is to enable the academic to become an independent designer and developer, through the maintenance of online content, over a period of time. However, it is also assumed that the Designer and Educational Developer would maintain contact with the project over a period of time. The triangles indicate the relative efforts of the critical members of the project team at each phase of the process, based on the influence model (Sims, 1997), which articulated the period at which factors had specific influence over the project. The allocation of resources to enable this process involves establishing "unit teams" whose commitment will vary according to the position of the unit in the development cycle, with expertise based on the varying requirements of the course. More importantly, within the context of our work environment, it is the allocation of resources for the duration of the project life that differentiates the model, as detailed in the following description of the phases.

Phase 1: Prepare Functional Components

The aim of this phase is to design and create a functional teaching and learning online environment that will meet all learning outcomes as well as faculty teaching and learning strategies. The first phase therefore becomes easier or simpler than more traditional models of instructional design, as it is functional, and production does not

BEST COPY AVAILABLE

try to complete a final package at the first attempt - the process can therefore be likened to enabling a "dress rehearsal" for both teacher and leaner. The process also involves specifying the *core items* for this phase, such as specific teaching resources (e.g. unit guides, study guides, readings), their mode of access (e.g. print, online) and the essential educational strategies (e.g. experiential, situated, learner-centred). In this way the academic who has minimal experience with online teaching and learning environments has an relatively easy introduction to the environment while knowing that ongoing support will enable the generational development of that environment. An equally important aspect of this phase is the allocation of team members and their specific role within the project, which can be articulated in terms of:

- *The Support Team*: Providing the Educational Designer (responsible for educational advice and curriculum design), the Interactive Architect (responsible for ensuring the online interactions and communications are consistent with the design) and Information Analyst (responsible for ensuring all required learning resources and objects are available). In addition, Project Management support will be required
- *The Faculty Team*: Allocating the Content Specialist(s), who are responsible for ensuring all necessary content is defined and that all learning outcomes, learning activities and assessment tasks are defined. In addition, a commitment to the schedule and baselines/guidelines is critical.

In addition, an Online Developer, Network Specialist and Technical Specialist will both advise and be advised on required and/or appropriate learning environments. Another aspect of the concept of *influence* is that members of the development team are understood to have potential levels of influence at any stage of the development and delivery process, although that influence will be affected by the current status of the project. For example the Interactive Architect, who has the main responsibility (influence) for creating the design specifications, may also be active in the quality review of the project as it nears completion. An important concept underpinning this model is that, like actors in a play, the team members all have roles to play and particular *scenes* or *acts* within that process will require their leadership. But they can also have smaller, but by no means unimportant, roles throughout the whole development, delivery and maintenance cycle.

Phase 2: Evaluate, Elaborate and Enhance

The second phase is conceptualised to take place during the delivery of the unit, with feedback from both teachers and learners used to modify and enhance the delivery environment. This may include the introduction of content items and enhancement of teacher:learner, learner:content or learner:learner interaction conditions (Sims, Dobbs & Hand, 2002). It is also an opportunity for teachers to work in a scaffolded environment to maximise the effectiveness of online environments, where the efforts of both teacher and learner can be evaluated and the delivery environment enhanced on the basis of that evaluation. This process also allows for clearer scheduling of resources and consequently planning, production and workflow processes.

This phase will require a *team-based* approach to delivery combining, where appropriate, both academic and technical staff in two discrete components. The first requires more technically-oriented teams to "shadow" the delivery of the unit materials defined and created in Phase 1 to both assess their efficacy as well as integrate additional content, interactive learning objects and collaborative activities. The second includes the provision of targeted professional development or scaffolding on an "as required" basis for all participants in the learning process. Overall, this phase emphasises generational changes with an increased emphasis on the production (completion) of resources, with the students or learners having the role of research or evaluation assistants. There is less emphasis on handover, and more emphasis on *duty of care* through the availability of sustainable course materials and teaching resources. It is by developing and building effective communication paths between each of these three groups that a shared understanding of the project goals and learning outcomes can be established.

Phase 3: Maintain

Following completion of the course of study, additional modifications and enhancements are prescribed and implemented for subsequent delivery. The unit would then continue in "maintenance mode", involving ongoing support and training, until it undergoes a more formal review. Again, the important concept underpinning this model is that the original functional system developed will always be subject to change and that any development environment must cater for resources to be available for the duration of the life-time of a course (or unit) of study. Within tertiary institutions this can be as long as five years, the time between a unit's conception and its formal review for reaccreditation. However, the sustainability of the course is catered for by the continual process of gathering and incorporating evaluation data.

2002		2003		2004

	Prepare materials for S3 units	Prepare materials for S4 units	Prepare materials for S5 units	Prepare materials for S6 units	
		Evaluate S2 units	Evaluate S3 units	Evaluate S4 units	Evaluate S5 units

Figure 3: Implementing the Plan

The success factors will depend not only on the concept being accepted but also for academic staff, students and the development team to reconceptualise their roles in the design and delivery of online educational resources. For teachers there is the option to collaborate with an online development expert while delivering the course to implement modifications based on student feedback; for learners there is the opportunity to contribute to both the content base and the educational strategies. Figure 3 demonstrates how the model may be implemented over a three-year cycle, with the assumption that units of study are delivered on a semester basis.

Conclusion

Higher education in Australia is changing. To meet these changes and challenges innovative models for academic support are required, and these are our initial thoughts on one such model. In the conference presentation we will introduce the work environments in detail, describe the advantages of the influence model for instructional design (Sims, 1997) and then detail the modifications to this model to enable our 3-step strategy to be implemented. The value of this plan is the innovative ways in which it conceives the development process, not as *design – develop – implement – evaluate* , but rather *develop baseline – implement/evaluate/develop – maintain/evaluate*. We believe this model has significant potential for higher education support units and look forward to receiving feedback on our concepts.

Distance Learning Needs in Indonesia Business Companies

(Survey Research Report on Distance Learning, 2000)

ABSTRACT

In dynamic competition we are facing today, the development of human resources in an organization play a vital role to enable the organization to sustain and compete with others. The emerging and convergence of information technology and telecommunication have come up with various application that support not only for the company daily operation but also for developing its human resources knowledge and skill through e-learning.

Distance Learning, where student and teacher are connected by technology rather than by classroom, is becoming a viable option to traditional teaching methods, and is poised for major growth over the next several years. According to Group Computing Magazine, Sept/Oct 1998, the percentage of large corporations with pilot online training programs in 1997 is 81% and percentage of corporate training departments planning take training online by 2000 is 50% and percentage estimated to be delivered in 2000 is 28%.

In Indonesia, distance learning has initiated formally by Indonesia Open University since 1984 by majority using printed module. Up to now the development of distance learning is still slow. As the technology is growing fast (eg: the internet) and the significance incremental of internet user, it has created an exciting opportunities for all to implement a technology based distance learning (e-learning).

In searching the needs of distance learning in business company in Indonesia, Information Technology Research Division of PT Telekomunikasi Indonesia, tbk did a survey research to "Top Companies and Big Groups in Indonesia", mostly they have a headquarter office in Jakarta, in the year of 2000.

The objective of this survey research is:

1. To identify the awareness level of using distance learning as corporate training activity.

2. To know the perception of distance learning in business company.
3. Try to find out the need of distance learning for corporate training and technology needed for distance learning.
4. To find out the market size of technology based distance learning and potential market of each technology.

The sample of the survey was taken from 585 companies (population of "Top Companies and Big Groups in Indonesia") with *stratified cut-off random sampling*. The stratification was done based on business category of the company. With 585 companies population and 10% bound of error, we found out 85 companies as sample for this survey research. The sample in each business category is chosen through linear systematic random sampling method. The survey research was done within May to July in the year of 2000 in Jakarta. The respondent of the company was requested from the top management of the company, especially from the training center department. In order to balance the information, from each sample also requested to provide another respondents; employee of the company who ever joined the course in the company training program (trainee) and the training instructor (trainer). The result analysis of these 2 respondents will not use to represent the whole trainee and trainer. The surveyor through the questionnaire interviewed each respondent.

DISASTER MEDICINE ONLINE: AN INTERNET BASED MODULAR CURRICULUM FOR HEALTH CARE PROFESSIONALS

B. Singleton, P. Parks, A. Lund, K. Lam.
University of Alberta, Division of Emergency Medicine, Edmonton, Alberta.

Background & Need for Disaster Medicine Training

Disaster Medicine (DM) training for healthcare providers is currently lacking within Canada and throughout the world. Until 1993 there was in existence a one-week Disaster Medicine (DM) course offered in Arnprior ON, Canada for physicians. The course was delivered in a face to face style that necessitated the students travel to the site of the course. The course is now defunct and there are no known plans to resurrect the course in the future. A needs assessment completed in Alberta showed that the majority of physicians (> 70%) felt a DM course would be both valuable and something they would invest time in taking. Although physicians were the target of the needs assessment, there is a dearth of DM training available to all types of healthcare professionals. Although the Disaster Medicine Online (DMO) project began prior to September 11, 2001, the events of that day are a tragic reminder that training in DM is a need for all communities.

In January 2000, the DMO working group at the University of Alberta began work on a Distance Education (DE) solution to the DM training deficit (www.disastermedicine.ca). As development began it became evident that this project could be applicable not only to physicians but to other health care providers as well. The DE model was chosen because of a number of advantages it provides to health care providers. The DE model allows for affordable, accessible, asynchronous, and active delivery of disaster training. If students are required to travel to one location for the course there is a large financial cost for travel, accommodation, and lost wages. Health care providers are busy and taking a week off for a course may be impossible. In order to provide the best possible learning environment one would hope to receive instruction and content creation from experts within the field of disaster medicine. These DM experts are in short supply, and also originate from geographic locations across the globe. By adopting a DE model of DM training, it becomes possible to unite a large number of students from varying geographical locations with the finite pool of DM experts. The DE model allows these obstacles to be overcome, and provides a great deal of flexibility to the DM students.

Given the vast growth and availability of the World Wide Web, this medium was selected to deliver an asynchronous style course. Being asynchronous and Internet-based allows students to take the course at times and places that are most convenient and least disruptive to work and personal responsibilities. The Internet and asynchronous mode also allows classes to consist of students from numerous countries and time zones.

The course site was created using a combination of hand coding HTML and Dreamweaver 4.0. Although the members of the Course Development Team (CDT) each worked on separate portions of the course, weekly meetings were held to review all content work. At these meetings decisions were made on changes to current work and timelines were created for future work. All members of the CDT were aware of work being done by the other members of the CDT. The CDT researched, wrote content, and created the web version for the pilot modules of the course. As future modules are developed the goal is to use expert writers for the development of course content. The CDT would then be responsible for adapting this expert content to a web format, with the goal of ensuring sound instructional design. A 'Writers

Guide' was created during the development of the first module as a resource for expert writers of future modules.

Description of Disaster Medicine Online

Disaster Medicine Online is a modular, interactive, asynchronous, Internet-based course. The modular concept allows for learners (physicians, nurses, pre-hospital personnel, administrators, etc.) to participate in core modules early on, and to continue through more specialized modules to their level of training and/or interest. Interactivity is accomplished by using Computer Mediated Conferencing (CMC) boards, course facilitator (online tutor), pre-tests, and conversational style language. We feel that interactivity and solid instructional design differentiates this course from a mere informational web site, and as such places DMO in the higher category of an educational course which utilizes the Internet as its delivery vehicle.

Disaster Medicine Online consists of six DM modules and one Welcome Week module. The Welcome Week module ensures all students have the necessary computer skills to complete the DMO course. The DM modules are made up of a series of lessons with each lesson having clearly stated learning objectives. Individual lessons are intended to be completed in one sitting and may have exercises or activities within them. It was assumed most students would complete the course in the order set out by the lessons, however a student who chose to omit or complete lessons in a different order would be able to do so. The majority of the course is text and graphics with some multimedia included. Feedback indicated the multimedia was interesting however often it did not add educational value. An attempt will be made to ensure future modules contain germane and pertinent multimedia clips.

The Computer Mediated Conferencing (CMC) board is a tool used to allow students to interact with each other and for the course facilitator to interact, assist, and direct learning. Each course has it's own CMC board that is used to pose and answer questions. The boards are also used to discuss topics initiated by the facilitator or students.

Despite being asynchronous the course is run with a finite class of students and a specified start and end date. Ensuring the students stay on track during the specified timeline is one of the many integral roles the course facilitator plays. In addition to time management, the role of the course facilitator is to aid in the interactions of the student with both the learning materials and with each other. The facilitator maintains frequent communication with the students via e-mail and the CMC boards. By being readily available the facilitator can deal with not only content questions and issues, but also administrative concerns and any student problems that may arise.

Assessment of the student is done by student participation on the CMC boards and a final assignment consisting of short answer questions related to the lesson content within the module.

Evaluation of DMO course

After rigorous peer review by the CDT the course was tested for usability issues related to the web course interface. Prototypical users were given multi-step tasks to perform within the course site. A silent observer tracked time to perform tasks, errors, and any tasks that could not be completed. Based on the feedback from this usability testing some minor changes were made, but overall the course was found to be easy to navigate and understand.

A panel of expert reviewers then reviewed the course. The expert review panel consisted of Medicine, Disaster Medicine, and Distance Education experts. As much of this expert review feedback as possible was incorporated into the course prior to the initiation of the pilot course. Some changes made at this point were content modifications and coding corrections to accommodate specific software and hardware.

The pilot course consisted of the "Welcome Week" and DM 101 modules. 22 health care professionals voluntarily enrolled in the course which was scheduled for a 3-week period. Demographics on student occupation and previous exposure to DE were collected. As well, data on the specific hardware and software configurations used by the students was collected. The evaluation of the pilot was prospectively created and consisted of (i) evaluation of the course site and learning materials, (ii) evaluation of the facilitator, and (iii) evaluation of the students in meeting the learning objectives.

Feedback from students showed the layout of the course site was easy to use and effective. The decision to ensure that the language in each lesson was casual and conversational, as opposed to textbook and academic in nature, was supported by 100% of the respondents. Throughout development of the course the 'lowest common denominator', those with slow Internet connections or little computer and Internet experience, was always kept in mind. This was also supported by 100% of respondents being satisfied with the 'download time' of the course site, as well as positive comments on the value of the Welcome Week. The respondents overwhelmingly felt the length and content of the lessons were appropriate and allowed students to meet the preset learning objectives.

The majority (86.7%) felt the CMC boards were a useful educational tool and 95% of students participated in the CMC during the course. Some comments indicated that in future courses the facilitator may need to take a more active role in ensuring everyone has equal opportunity for input. It was felt by some that those that responded early on were able to say all that needed to be said. The majority of students felt the facilitator provided enough guidance and adequate communication throughout the course.

All students felt the course material was useful in meeting the learning objectives and this was evident in the outstanding student results on their final assignment.

Conclusion

The DMO Internet-based course represents an important innovation in disaster medicine training for healthcare professionals. Using distance education methodologies, sound instructional design, and simple web development, a platform for delivering quality education to healthcare providers can be achieved.

Interactive Graphic Organizers

Thilla Sivakumaran, College of Education, University of Tennessee, USA,
sthilla@hotmail.com

William Wishart, College of Education, University of Tennessee, USA,
wwishar1@utk.edu

Abstract: Graphic organizers are a way of visually representing information or concepts and may be built with text or graphics. The educational value of graphic organizers has been well documented and their use has become an important part of many instructional models. There are many books and websites with graphics organizers but none have interactive components where the students can try their hands at creating a graphic organizer. What we have created is a website that gives the students the definition, example and also an interactive component which the students can try once they understand the concept. This process allows the students to learn the information, process it during the example stage and then apply it in an interactive module phase. By providing a way for the students to progress through all three phases of the learning process we can increase the chances of them understanding graphic organizers and benefiting from this powerful tool.

There has been little research in the area of computerized interactive module. The studies that have been done in the past centered on creating computer based tutorials or simulations for traditional classes. Petty and Rosen did a study on tutorials and simulations that they created for their students in an experimental design class. The students who used the tutorial and simulations had higher test scores compared to those who didn't (Petty and Rosen 1990). The students also reported that they enjoyed using the program and that it was a positive experience (Petty and Rosen 1990). In a similar 1995 study Chaprarro and Halcomb used a computerized tutorial called STAR (Self-Test and Review) in a computer-managed general psychology course (Chaprarro & Halcomb, 1995). The students (n=136), who voluntarily used the tutorial to study for multiple-choice quizzes comprised 49% of the research group (Chaparro & Halcomb, 1995). Results indicated that, across both section types, the students who used STAR as a study tool achieved better course performance than the students who did not used STAR (Chaparro & Halcomb, 1995). In 1983 Kulik, Bangert, and Williams looked at integrating computers into the classroom. The analysis showed that computer-based teaching raised students' scores on final examinations by approximately 0.32 standard deviations, or from 50th to the 63rd percentile (Kulik, Bangert, and Williams, 1983). In addition, questionnaire responses showed that students who were taught on computers developed very positive toward the computer and positive attitudes toward the courses they were taking (Kulik, Bangert, and Williams 1983). Another fact found in the study was that it reduced the amount of time that the students needed to learn the material (Kulik, Bangert, and Williams 1983).

Studies have shown there is evidence to suggest that computerized tutorials help students learn better. What we have done is create Interactive computerized tutorials using a macromedia program called Flash. The modules created were for Graphic Organizers. Graphic organizers are a way of visually representing information or concepts and may be built with text or graphics. The benefit is being able to see visual patterns and relationships, which allows the development of better insight and understanding of information. The parts that make up an organizer have little value but put together provide the "big picture". The educational value of graphic organizers has been well documented and their use has become an important part of many instructional models. There are a number of programs for creating electronic graphic organizers such as Inspiration or Kidspiration but we have found using macromedia flash provides the opportunity to include an interactive component that allows the development of a more complete and self-contained learning module. There are many books and websites with graphics organizers but none have interactive components where the students can try their hands at creating a graphic organizer. What we have created is a website that gives the students the definition, example and also an interactive component which the students can try once they understand the concept. This process allows the students to learn the information, process it during the example stage and then apply it in an interactive module phase. By providing a way for the students to progress through all three phases of the learning process we can increase the chances of them understanding graphic organizers and benefiting from this powerful tool. It is important that the students are able to apply what they have learned and that is where the interactive module plays a key role.

The modules first phase, where the students get the information has a voice over which allows the students to hear as well as see the explanation. In the example stage, a flash animation with a voice over explains how the graphic organizer is used. Once the students have gone through the first two stages, they can try the interactive piece. This component provides an opportunity for them to use the knowledge they have just acquired. Students, when looking at an example or definition, may think they understand the concept but when they try to apply it, they are lost. Our method allows the students to test their understanding right there and then, and receive feedback. If they don't fully grasp or understand the concept they can refer back to the other two phases for help. The ability to actively use the newly acquired knowledge, receive feedback, and additional instruction or testing as needed makes this approach unique. This paper will focus on the opportunity and potential of using Macromedia Flash in this type module approach. The modules that are created will be the used in future studies to determine the effectiveness as a treatment or instructional tool. It is our belief that their use will provide improved student interest, participation and achievement as compared to traditional instruction or modules lacking the interactive component.

TEACHING CREATIVITY IN COMPUTER SCIENCE TO THE PLAYSTATION GENERATION

Stephen Skelton
Lecturer in Games Development, Interactive Television and Advanced Multimedia, UNITEC, Auckland, NZ, Owner of Maia Digital Ltd (Games Development) and Channel You Ltd (Interactive Television)
skeltand@xtra.co.nz

Abstract

*The success of today's computer science educational institutions hinges on successful innovative and creative learning strategies. This involves integrating new media technologies such as the latest console games and digital television, which our current Playstation generation has been brought up on. The fact that the games industry has outstripped Hollywood as a multi-billion dollar earner and is still growing (at approximately US$15 billion worldwide) is indicative of this influence. How do we bring the inspiration that is needed to be the next Electronic Arts into our classrooms and labs? This paper will examine these issues and is designed to explore innovation in new media, using the example of games and interactive television. I propose that if we want to attract the next generation of Playstation creatives into our classes, we must use media they are familiar with, expressed with tools that are truly engaging, interactive and exciting. We need to incorporate a creative theory for computer science... Energy (excitement) = (what) Matters * Cutting edge technology (squared = exponential growth).*

Keywords
Creativity, Innovation, Games Development, Games Design, Games Programming, Artificial Intelligence.

Introduction

The console war is heating up and the computer game superpowers are demanding more and more reinforcements from the computer science institutions.

You enter the lab. It is dark and warm with heads focused on monitors, emotion alive in the faces of all around. This is the online games testing room in some of the major universities around the globe who have realized the potential of the games industry in awakening the minds and imaginations of the Playstation generation. I am particularly interested in how we awaken that inner spark of learning, how we excite and uncover our potential Einsteins, whether it be in our students or in ourselves. In order to do that I have blended the latest in technology (games development and the medium of digital interactive television) in a series of courses designed to ignite the next George Lucas or Shigeru Miyamoto (the creator of Zelda).

Why is it that students of today are fascinated with learning through this intense medium of games? Primarily it is because it is exciting when we discover new knowledge, can find satisfaction and success in what we are doing...and have fun in the process. Games do this.

When students first come into the class they are often struggling to learn the basic skills of computing and new technologies, tend to feed back the instructions we give them and generally vanquish the thought of anything innovative initially into a far flung corner of their mind. What if we were to encourage this innate creative skill in their courses right from the word go?

Using a variety of techniques and skills drawn from software application methodologies (Macromedia, Microsoft), game structures, interactive digital media and applied physics we can challenge the boundaries of what we thought our students were capable of and open the blocks to our/their true innovative and creative power.

The New Games Industry

Take away the pain of the tech crash of April 2000 and you still have information technology making up the backbone of the world's economy. In Japan, DoCoMo, the mobile arm of telecom giant NTT (which signed up 30 million Japanese mobile users in two years) delivers games in a form that can be easily displayed on a cellphone. Sony spent over US$800 million in development of Playstation 2. And in the area of new delivery platforms, in the UK on BSkyB, for example, one interactive TV channel, Playjam, has 1.8 million viewers playing 30 minutes of games four times a week.

BEST COPY AVAILABLE

The Even Newer Teaching

This new economy is demanding. All of us teaching in this area are aware of that; huge enrolments, big demand, heavy course loads and marking. And so often the technology takes precedence over the human spirit, takes pride of place over creativity, the flame that brings us the George Lucas of new technologies. There is such a diverse group of computer science professionals demanding new and innovative ways of approaching the new economy. And there are indications we may need to be more expansive and think outside the square, in the way we teach the "new" science. The ACM SIGCSE Bulletin found shockingly low performance on simple programming problems. In a recent job test in Auckland, NZ, amongst 300 applicants for a web developer's position, less than 10% completed basic coding problems in HTML. There are alarming numbers of women that drop out of computer science courses primarily because they perceive the courses to be too technical with little space for their own individual creativity. The American Association for University Women's report, *Tech-Savvy: Educating Girls in the Computer Age* pointed out that girls found programming classes tedious, computer games boring or violent and would rather have input into the design of simulation, strategy or interactive media and games.

Playing The Game

I propose that we are often using outdated methods to teach our students computer science. Too often we are teaching courses in the same way we learned them. Computing is so different today. We must excite our students by the same innovations that are embracing the new economy.
The processes that are used in current industry games best practice might help us all to be innovative. It involves a process of

a) Setting up a "business" – this gives the students/groups an identity
b) Evolving a team, roles and a methodology – this involves a commercial group production process
c) Creating a schedule for envisioning, storyboarding, designing, testing and releasing
d) Building an educational or commercial game in 3D Studio Max, Maya, Director or Hash for a real client where possible
e) Presenting the "finished product" in a "celebration", that is exciting, that matters because it is relevant.

The Special Theory Of Creativity

E is for energy and excitement

E is for the energy and excitement that students feel when they start working with media in this way that means something to them, in fields like games and interactive television. When students are motivated in a subject area this is a key ingredient to achieving a breakthrough, on the path to innovation and creativity.
Games do motivate people, from the action, combat and strategy games that men indulge in to the chat, communication and strategy games that women enjoy.

M is for " what matters"

When we are engaged in creating things that matter to us, our mind is engaged, we see a purpose, we link practical achievements and tasks making sense in the real world and link them with activities that bring us success, joy and happiness. Our success compounds, creating "mass", accumulating events that matter in our consciousness. Through technology today we are even developing a parallel "universe" of reality in virtual reality applications where a person who has a phobia of spiders, for example, can interact with a "virtual spider" to overcome their fear. The relationship of mind to matter and the power of "events that matter" in our motivation should never be underestimated. Even at a quantum level in the famous photon splitting experiment it has been proved that experimenters have an influence just by thinking an outcome, which in turn affects the experiment. So when we think that something "matters" it profoundly affects the way we interact with our learning environment at a very deep level.

C is for "cutting edge"

C is for celeritas, swiftness, being on the edge of current development, reaching out to students through THEIR current media, THEIR up to date modes of expression, not living in the "past" of what we were brought up in or how we were taught. So upskilling, retraining and networking with the "cutting edge" research in our field is ever more critical. This enables us to bring our teaching to the market at the speed of light (= delivered on the cutting edge), linking excitement to what matters and practical achievements, thereby amassing success.

Squared is for "accelerated growth"
There is no doubt that the next 10 years of human evolution herald a previously untapped source of ingenuity that could be put to good or destructive force. We have nuclear power and weapons, the genome and genetic modification of cells, virtual reality and breakthrough discoveries into cures for many of our known diseases. Dr Valerie Hunt, in her book *Infinite Mind*, detailed an experiment by a group of computer scientists from Stanford University who programmed in the tremendous explosion of technological development and scientific knowledge coming into the world today. They asked the computer to plot the great discoveries of the world, beginning with the wheel, through the printing press, the steam engine and the splitting of the atom to the computer itself, and to project into the future and predict great upcoming discoveries. The projected computer pattern went completely off the graph at the year 2011. During the last minutes of the year 2010, the computer predicted 18 discoveries that equal the splitting of the atom. A Harvard Cyperposium (Feb 10, 2002) highlighted hot trends of the immediate future including artificial intelligence, with future robots relying on AI applications being sent into dangerous situations for police and military use (an application that has been employed in Afghanistan). Within 50 years the predictions are that AI will be on par with human intelligence.

The New Wave In Thoughtful Games

The future of games is unpredictable. We all know how fast the industry is moving. When you start making a game, you know that by the time you finish it, the whole industry will have changed.
The current trends and future are promising and have spin offs into many other areas of development

- Movie quality graphic s, ever more beautiful, realistic and 3 dimensional
- 3D cards capable of taking more and more workload off the processor
- Virtual reality at home
- Improved Artificial Intelligence (AI)
- Serious physics engines which power intelligent game worlds

Some current and future developments in AI, for example, herald this "intelligent reality".
As an example, John Taylor, the Professor of Maths at Kings College, London is "growing" an advanced artificial intelligence that he claims will give baddies brains to rival your own. The "mind" is called LAD or Language Acquisition Device.
Traditional AI grew out of efforts to crack enemy codes in WWII. Ever since Steve Grand, a self taught programmer, set out to design the first AI computer game in 1992, using ideas from neural networks, genetics and chemistry to design a rough brain biochemistry for a new breed of virtual pet, AI has been part of computer games. He called them noms and marketed the game as Creatures in 1996, creating a huge hit where players developed strong emotional ties to their creatures. Richard Evans at Lionhead Studios has created Black and White, where you aim to rule the world as a god and must win the devotion of your people. To help you win followers you have an artificially intelligent assistant.

Into The Game

Game Design

In teaching courses to the Playstation generation on games there are some basic principles we must follow to fulfill the special theory of relativity.

a) Go for a broad audience – your games and teaching must embrace both a male and female audience
b) Innovation is the key – look at cutting edge applications and help your students to create these – Myst was a winner in its time with beautiful graphics, the Quake engine is regarded by many as the staple of physics games engines, Age of Empires was one of the first with a historical theme and multiple victory conditions
c) Design by playing – teach by doing it yourself first
d) Include critical decision making as part of your gameplay and classes
e) Start with introducing prototypes and testing early
f) Make the first minutes of gameplay and classes very exciting
g) The player must be the hero or heroine (not you as the designer or programmer). Engage their minds…after some sweat they must reach victory
h) Get the player and student to invest in your game and classes – help you to build the game as a group and build assets e.g. use Half Life in architecture design or gmax to add assets to Dungeon Siege

i) Create a great story and excellent storyline – it's at the basis of every culture
j) Create a series – help your students to think about characters that can develop (like Lara and Zelda) and games that create franchises (like the Star Wars series). Similarly find the links to other courses and encourage practical end of degree thesis or project work to encompass the same professionalism that you introduce
k) Pay attention to detail e.g. graphics, sound
l) Create an intuitive interface that's easy to use
m) Provide a multiple of different experiences, from single to multiplayer (individual to group assessment), cooperative play and so on
n) Games are an art and so are unpredictable like life – it means you have to balance what you can do practically (your budget and schedule) with what you dream/envision (the quality)
o) Test, test and test again

Game Programming

So many of my students come to class disillusioned by programming, but when they apply it to games and can see the result of their work in a short space of time in 2D or 3D spaces, the light of awareness and accomplishment dawns and they get excited, filled with energy. Suddenly it matters, it has an affect on "mass" in the real world, it does something they can relate to (games and television) and it launches them at high speed into the very lucrative area of games technology. Engaging students in exciting and energizing tasks is crucial to deep learning. These Playstation or MTV fans have been profoundly influenced by this sort of media so why not indulge them by immersing them in it to create breakthrough creativity. And this may also be exactly the type of breakthrough mediathat computer science students want the opportunity to produce. Typically, women, for example, are interested in computer science that is creative, and drop out of courses they perceive to be overly technical.

The General Theory Of Creativity

So if we see this opportunity, to revolutionize the way we see the universe and computer science through excitement and creation of media that matters with the delivery mechanisms of cutting edge technologies, then we begin to curve the very fabric of time and space, providing alternative paths of reality into computer science for students where before there was none. The more human mind energy or mass that is gathered in any one spot, such as now, as you are reading this, in this spot, the more space and time will be curved around it = MORE BREAKTHGROUGH. In creating this we are also creating a portal for students to come to, an intelligence and reality, another book in the divine library waiting to be read.

Conclusion

The special and general theory of creativity leads to the conclusion that the more minds we can gather either virtually or in reality around this new, exciting, cutting edge area of research, (a subject that has mattered to us all from the moment we first started to kick a ball) the more powerful the wave generated for breakthrough creativity. Recent conferences, the establishment of e-journals and a growth in research interest in digital games have started to raise the profile of gaming research and go to show how vibrant this rapidly developing field is. To encourage this growth, support collaboration and minimize duplication of effort it is suggested that there would be benefit to the digital games research community in establishing its own international association, currently at http://www.gamesconference.org/network/ These activities would help to raise the profile of the emerging field of computer game research in a manner similar to that found in other academic fields of study. I look forward to the possibility that many of you reading this article might also want to join us on this journey.

FORMING COMMUNITY with TECHNOLOGY: THE DEGREE PROGRAM PLANNER

Deborah J. Smith and Evelyn K. Ting,
Empire State College, Saratoga Springs, NY
Email: Deborah.Smith @ esc.edu, Evelyn.Ting @esc.edu

Abstract: Empire State College students, in the online Educational Planning courses, attempt to build a virtual community while formulating their unique college degree plans with a web-based Degree Program Planner to input data in a standardized format. The DP Planner builds a shared community of practice--extending the capabilities of the course management system with task support in formatting the degree plans and enabling discussion of the student's evolving degree plans with their mentor and classmates in the course.

Introduction

Today's students see networked education as one option for attaining a college degree without having to entirely rearrange their lives. Computers, the Internet and software applications give many students a unique access to learning. However, the general capabilities of a course management system (CMS) may not support all types of student assignments. In this case, a custom software tool can facilitate students' assigned tasks, permitting them to focus on their interactions with each other rather than the technology. This presentation will examine the use of one software application with adult students preparing their college degree plans.

Learning Online

Grygo (2000) identifies factors essential to effective online communities including common goals, clear benefits of interaction, content geared to needs, and transparency. In educational circles, these principles are learning goals, curriculum presentation and interactions (member development); instructional media/tools (asset management) and learner support systems/services (community relations) (Ragan, 1998, Williams and Cothrel, 2000).

There are several elements that assist learning, including knowledge in a context of a community of practice, coaching and flexibility. The skills of a *community of practice* (CoP) are learned by increasing the complexity and scope of tasks the member undertakes in a specified context, from beginner level to expert knowledge within the community (Lave & Wenger, 1991).

Burton, Brown and Fischer (1984) examine student coaching as an important aspect of the learning process. Coaching assures proper skills acquisition, gives clear instructions, turns negative elements into constructive ones and critiques progress to recognize errors.

Student Experience and Instructional Design

In creating a networked student experience, an interactive model poses questions for the design process: What is the *goal* of the experience—after the student is done interacting, how will they behave differently online and in real life as a result of the interaction? Given a defined goal, what *experiences* assist the student in achieving the goal? At the heart of every interactive design project should be the question "What cool things can the *student* do?"(Kozel, 1995).

Good design must reflect these points. In networked experiences, where the student environment is crafted to be consistent, predictable and transparent, the critical parameters are *visibility*: allowing students to see what to do and what they might do next ; *conceptual metaphor*: which the designer chooses to present for the student experience; *good "mappings"*: allowing the student to identify relationships between their actions and results and *feedback*: letting students know what their actions have caused to happen (McAdams, 1995).

Mentors and Students at Empire State College

Founded in 1971, the Empire State College mission is educational access and quality with a goal of establishing new ways of teaching and learning. The college offers adult learners undergraduate and graduate degrees in geographically dispersed "centers" around New York State, through distance learning and weekend "residencies."

Students complete courses in their own home, within their own timeframe. At Empire State College, a primary belief is that learning occurs anywhere, not just in traditional academic situations. Individual faculty-student interactions, a variety of study models, prior learning credit, customized degree plans, and year-round enrollment serve to eliminate time, curriculum and access problems for students (Lefor, Benke and Ting, 2001).

Increasing enrollments and the speed of modern society produce students with pressing, pragmatic goals. Students today are often mature learners who come to the college with a distinct goal in mind; they look to their faculty member (known at Empire State College as a *mentor*) for an academic trail to reach this goal. In a shift from traditional advisement, the collaborative aspect of Empire State engages both mentor and student in formulating goals and degree plans for the student's unique educational path.

The Degree Program Planner

The pivotal document for a student at Empire State College is the individualized Degree Plan (DP) developed through mentor-student collaboration in Educational Planning (EP) courses. The student-generated Degree Program drives advisement, rather than traditional approaches of "one-size-fits all" imposed on the student by the institution. Traditionally, development and writing of the DP and rationale involved the mentor and student only, or a small in-person study group, while clarifying the framework of a student's program of studies.

Empire State College established Educational Planning (EP) online recently. Mentors assist with the two-part Internet course, enabling students to participate in private discussions with their mentor and interactive asynchronous discussion with other students in the course about their degree plans. An iterative discourse emerges among a diverse group of students and faculty where learning can be shared anytime, anywhere.

The active construction of knowledge from an adult learner viewpoint was EP 211's goal. In EP 212, the focus narrows as discussion and written work center on sample degree plans and rationales for the student's own studies at Empire State. Development of the DP is a mentor-student conversation, but DP submission is done in standardized format to the College Assessment Committee, for formal review as an academically sound program of studies. During the first two offerings of the course, students spent considerable effort achieving the correct format, then found they had trouble sharing their plans in the course space due to limits of the web and the variety of word processing software used.

In 2001, Empire State piloted an online Degree Program Planner (DPP). This Lotus Notes Domino web application using JavaScript formulates a student's DP online and allows discussion between students, their mentors and Educational Planning classmates in the Planner itself. In the DPP, students record college courses for which they are requesting transfer credit, Credit by Evaluation components (CBEs) and Empire State College studies they wish to take towards their degree. Students work on the DP over time, as the software automatically re-calculates credit totals and formats the student's plan in the prescribed format. Each plan has a discussion area, permitting all members of their EP course group to see and comment on a student's proposed degree plan.

At any time, the student can email the mentor a "Request To Review" statement with a link to the draft DP and asynchronous chat capability for mentor-student comments on revisions. Learning options in Educational Planning now range from individual work to a community of practice, where the practice is reflection on one's proposed course of study at Empire State College. (Lave & Wenger, 1991).

Summary

The Empire State College independent study model has broadened, using technology and virtual communities, to meet the educational needs and networking capabilities of adult students. The DP Planner helps build a shared community of practice by extending CMS capabilities: providing more task support in both plan formatting and discussion of evolving degree plans with a student's mentor and classmates in the course.

Web-based Support for "Teaching for Learning"

Ronald A. Smith and Paul Lam,
Education Office, City University of Hong Kong
Hong Kong SAR
ron.smith@cityu.edu.hk

Denise Chalmers,
Teaching & Educational Development Institute, University of Queensland
Australia

Abstract: There is compelling evidence that students' learning could be improved if individual teachers taught learning strategies to their students in the context of teaching their subject matter. As part of two-year "teaching for learning" project over 70 staff were trained and supported first to learn how to, and then to teach learning strategies to their students. In this paper we report on the final version of the web support http://edo.cityu.edu.hk/t4l/ that has been developed to support staff in "teaching for learning."

Introduction

The purpose of teaching is to foster deep and lasting learning. While learning can occur, and often does, without the benefit of teaching; teaching has no other purpose than to enable learning. Many universities offer programs to their students and to their teaching staff for the purpose of increasing the skills and abilities of their students as learners and of their staff members as teachers.

Student development and student learning centers offer programs, usually of short duration, to students to help them to improve not only their ability to learn (for example, study skills, time management, etc.), but also their abilities to demonstrate their learning (for example, paper writing, exam taking, etc.). In addition, some universities offer credit-bearing courses to students designed to better prepare them for success at university and beyond. City University has such a course, *Learning to Learn* (Kwan & Ko, 2000).

Staff development centers offer a wide range of programs and activities designed to help staff to improve the individual teacher's teaching skills, encourage the incorporation of new methods or technology into teaching, and support the development and (re)design of teaching plans and materials. The project described in this paper is an initiative of the Centre for the Enhancement of Learning and Teaching, a staff development unit. It is designed to encourage and support staff to teach learning strategies to their students within the context, and as part, of their regular courses in the disciplines.

One of the major concerns about learning skills/strategies programs is the lack of transfer beyond the general or generic training sessions into classes or courses in the disciplines. In a meta-analysis of the results of skills interventions on student learning, Hattie, Biggs and Purdie (1996) concluded: "The results of this meta-analysis support the notion of situated cognition, whereby it is recommended that training other than for simple mnemonic performance should (a) be in context, (b) use tasks within the same domain as the target content, (c) and promote a high degree of learner activity and metacognitive awareness. … In other word, effective strategy training becomes embedded in the teaching context itself" (p. 131).

Fuller, Chalmers, & Kirkpatrick (1995) have demonstrated that learning strategies could be taught to students within the context of a course and that this led to improved student learning outcomes. Further work (Chalmers & Fuller, 1996; Chalmers & Fuller, 1999) demonstrated that teaching staff could be successfully trained to teach learning strategies to their students. Their research has formed the basis for the project at City University.

Teaching for Learning Project

The project *Teaching for Learning: Learning Strategies for Students and Teachers* (Smith, 2001; Chalmers, Smith and Lam, 2002) grew out of the observation that the students coming to CityU were not as well prepared for university-level work as we would like them to be, together with the concern that they might be leaving without having acquired adequate study skills and learning strategies to support and sustain lifelong learning. In addition to the programs already offered at CityU, the *Learning to Learn* course, the oral and written communication courses offered by our English Language Centre, and the workshops offered by our Student Development Services, we felt it was necessary and appropriate to directly involve more of the teaching staff in working to solve this problem.

The *Teaching for Learning* project was supported by a two-year Teaching Development Grant from the UGC. One of its primary objectives was to develop materials for staff and students to support the teaching and learning of learning strategies. This paper describes the web-based materials created to support teachers in: choosing which learning strategy to teach and planning to teach it, teaching it, and follow-up steps including evaluating, documenting and re-designing it for the next time.

All teaching staff are very busy people with multiple demands on their time. Thus, it was necessary to provide the participants in the project with as much support as possible, particularly during the initial stages. In addition to expert help from the project staff and their colleagues, we thought it was necessary to develop web-based materials that could be used by the participants and that would last beyond the duration of our funding, June 2002. Various resources were developed and field-tested with staff and students during the project. They have been modified and this paper presents the "final" version http://edo.cityu.edu.hk/t4l/ that is being offered to teachers within CityU and beyond.

The approach to teaching learning strategies is based on the work of Chalmers and Fuller (1996) who present 23 different learning strategies. See Table 1.

Table 1. Learning strategies to be covered in the site, classified into four categories

Learning Strategies			
Strategies for acquiring information		*Strategies for working with information*	
1	Accessing information	9	Explaining ideas
2	Identifying main points from lectures and readings	10	Generating questions
3	Memorizing information	11	Making concept maps
4	Note making for assignments	12	Organizing ideas
5	Note making from lectures: following the lecturer's structure	13	Using a systematic approach to learning
6	Note making form lectures: Using a structure developed from prior reading	14	Using study groups
7	Note making from text	15	Writing paragraphs
8	Skim reading text	16	Writing summaries from notes
Strategies for confirming learning		*Personal management strategies*	
17	Analyzing a question and planning a response	22	Coping with the student role
18	Answering multiple choice tests	23	Study and time management
19	Assignment preparation		
20	Learning from feedback		
21	Preparing for essay examinations		

The site is structured to provide teachers with all the necessary information and tools they might need in order to teaching learning strategies to their students. It contains 4 major sections, each with numerous subsections. See Figure 2.

The first section, "Why teach learning strategies," provides the rationale for teaching learning strategies in context, as well as what other teachers and experts have said in the form of text and video clips, and addresses the concerns and worries of both staff and students.

The next section, "Choosing a strategies and planning to teach it," represents the heart of the site. It begins by providing staff with two ways to choose a learning strategy to teach. They can simply select one from the list of strategies (Table 1). Or alternatively, they can review a list of problems in learning that their students exhibit, pick one, and a learning strategy will be automatically chosen.

BEST COPY AVAILABLE

Table 2. Sections and subsections of the *Teaching for Learning* site

MAIN SECTIONS	SUB SECTIONS	Main Content
Why teach learning strategies?	What are learning strategies?	• Definition • Classification • Readings
	What are the benefits?	• Better learning • Better motivation
	Why teach them in context?	• More focused • Transfer of skills • Use skills in context • Problems with teaching out of context
	What other people say?	• Denise Chalmers • Maryellen Weimer • City University experiences
	Problems/worries	• Teachers' worries • Students' worries
Choosing a strategy and planning to teach it	How to choose a strategy	• Pick a strategy from the list • Analyze students' learning problems
	Where to teach it	• Outside class time • Lecture • Tutorial
	Creating methods and materials	• Customizable Web Pages • On-line tutorials • Lesson plans • Handouts • PowerPoint slide shows
	When to teach it	• Guidelines for deciding • A few good times
	Keys to success	• Integrate it into the course • Motivate students to learn • Model the skills
Teaching the strategy	Gaining support	• Peer support • Students' support • Support from others
	Evaluating success	• Students' feedback • Students' improvement • Other observations
	Documenting your work	• Portfolio • Video/audio/written • Case study
Next steps	Sharing your experiences	• Places to share your experiences
	Planning improvements	• Reflecting on the experience • Developing future plans

For each strategy selected, the "planning to teach" section systematically guides the teacher through decisions about where it will be taught (in class, in tutorials, outside of class; that is student self-study), when in the semester (a course calendar is provided), and what teaching materials to use. All strategies come with lesson plans, handouts, power-point presentations that can be customized to suit the teacher and his/her course. Many of the strategies also have customizable web pages that can be created by the teachers and then made available to their students. Each of these pages comes with several pre-set options that the teacher can select, plus includes spaces for the teacher to add their own unique information. This section also provides some suggestions for successful implementation, based on the research and suggestions for project participants.

The final two sections "Teaching the strategy" and "Next Steps" provide the teacher with advice on gaining support and cooperation from students and colleagues, evaluating and documents their work, and sharing their experiences and planning improvements.

The site has several special features that are particularly noteworthy. In addition to customizable web pages for students and various types of teaching materials, the site can also store the teacher's plans and allow them to return to the site to revise them. Of course, the teacher can also download his/her own plans. The project has also developed other web materials for teachers and students that are incorporated into this site. These include:

- "On-line Questionnaires: Student Learning Styles and strategies" http://celt.cityu.edu.hk/inventory/questionnaires.htm — this site that allows individual students to assess their own learning styles and strategies using four different instruments and to receive their own individual report, together with suggestions for how to improve their effectiveness as a learners. This site also enables CityU teachers to request all the students in their classes to complete a questionnaire. The students receive their own individual reports and the teacher gets a report on the class profile together with suggestions for how to better teach to the various styles/strategies.
- "Learning: Styles, Motivation and Strategies" http://celt.cityu.edu.hk/inventory/strategies/student.htm — this site designed by students and for students. It contains advice, exercises, games, questionnaires and programs to help students to better understand their own learning styles, and to improve their learning motivation and strategies. There is also a section where students and teachers can talk about how to learn more effectively. Students can access this site on their own, or teachers can suggest their students visit it.

In conclusion, this paper has described the content of a web site created to support teachers in teaching their students learning strategies in the context of teaching their course content. It is part of a larger two-year "Teaching for Learning" project and represents the final "deliverable" on the grant. It is based on the feedback we received during the training session with teachers, their reactions to earlier versions of parts of the site, as well as feedback for students. We believe it will provide a useful resource for all teaching staff, both inside and outside CityU after the project is completed.

THE LINKS PROJECT:
A USDE TECHNOLOGY INITITIATIVE

Sharla L. Snider, Ph.D.
Department of Family Sciences
Texas Woman's University
USA
ssnider@twu.edu

Abstract: Learning and Integrating New Knowledge and Skills (LINKS) was a federally funded technology project designed to integrate established and emerging technologies into the teacher preparation curriculum at Texas Woman's University (TWU). The project was supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology grant over a three-year period. The LINKS project encouraged institutionalized efforts for the teacher education program to address technology proficiencies desired by the schools and delineated by the professional associations. The project prompted changes in university faculty involvement and roles, technology curriculum content and delivery, and preservice teachers' performance and responsibilities in field-based locations. The purpose of this paper is to provide an overview of the LINKS project including final institutionalization efforts.

Perspective

The technology training received by preservice teachers is inconsistent and not focused, a problem stemming from the minimum levels of technological training at many institutions (McCannon & Crews, 2000). Instead of computers being used to their full potential, computers are often used for preparing instructional materials and not necessarily for student interaction. This is painfully true for a majority of female preservice teachers, who lack extensive experience and access to technology. These limitations are recognized by teachers, causing them to be concerned about their inability to integrate technology into the curriculum (Ertmer & Addison, 1999).

Related to this is the trend encouraging students and faculty to use technology throughout all aspects of the university curriculum. Teacher Education programs must focus on teaching how to use and integrate technology in the classroom (Brown, 2000). Additionally, the effectiveness of educational technology in enhancing and affecting student learning and achievement needs to be evaluated (Jones & Paolucci, 1999). New forms of learning aided through the use of technology have the potential to prepare students to be productive, critically thinking citizens (Gunderson & Anderson, 1999; Shive, 1999). Technology can also help teachers make their instruction more culturally relevant to the student's individual situation. Since multimedia, hypermedia, and the Internet have the potential for facilitating teaching and learning, it is of utmost importance that future teachers know how to use these tools (Duran, 1999; Johnson, 1998). In order for preservice teachers to successfully integrate technology into their classroom, they must be taught through faculty modeling the use of technology and in contextualized, subject specific settings. Ideally, all faculty members teaching preservice teachers at any point in their college education will model technology integration (Vannata & Beyerbach, 2000).

Overview

Learning and Integrating New Knowledge and Skills (LINKS), was designed to enhance the teacher preparation program at TWU by insuring systemic integration of technology into the curriculum. Three strands of the LINKS project addressed the technology needs of future teachers by supporting their development as well as the associated development of their mentor teachers and university instructors. Preservice teachers in professional coursework received specific instruction on campus as Interns I, II, and Residents as well as extended experience in the field, and they completed much of their coursework on-line using TechTrek, the web site designed to support their efforts. In field settings, LINKS personnel encouraged the awareness of mentor teachers so they could be more supportive of the attempts of preservice teachers to use technologies in instruction. Finally, university instructors of courses leading to certification were offered instruction in web-based course delivery so they might provide a model of technology integration in their own curriculum design and delivery. The LINKS program evaluated the progress toward the program goals for these three different populations, future teachers (n= 300), mentor teachers (n= 85), and instructors (n=90).

LINKS Beginnings and Development

This project was funded September 1999 through a United States Department of Education (USDE), Preparing Tomorrow's Teachers to Use Technology grant. At the time of funding, the professional preparation sequence for teachers administered in the College of Education did not include an education technology course or a means to assess computer literacy. The goal of the LINKS project was to build on the current technology integration efforts to establish a structure for instruction in and benchmarking technology skills of the preservice teacher. This goal was to be accomplished through a systemic expansion and ultimately formalized institutionalization of the integrated technology concept for preservice teacher educators. In order to impact change, three populations were supported: students, inservice teachers, and instructors.

Students. With USDE support, the LINKS program refined the integrated technology component and delivered it in collaboration with the field-based education program. Curriculum delivery included large group instruction, lab instruction, and distance education support through a curriculum website (TechTrek). The three stages of the LINKS program were developed for the three semester professional sequence designated as Intern I, Intern II, and Resident. The curriculum standards were provided a framework from state and national standards and offered students a variety of indicator possibilities for documentation of their performance. To track student progress, the Technology Passport was developed and published electronically and in printed form. The Technology Passport tracked student progress, and alerted professors in both the Colleges of Professional Education and Arts and Science to technology expectations and standards as they related to content areas and the state standard for technology applications.

Inservice Teachers. Each semester, Interns interacted weekly with inservice teachers functioning as mentors during classroom observations. Mentors participated in on-campus training sessions and received assistance designed to encourage their receptivity toward technology use. During Residency, preservice teachers were paired with supervising teachers for their student teaching experience. A select group of supervising teachers participated in specialized training dedicated to creating classroom appropriate technology products for use and evaluation in the classroom setting. Both supervising and mentor teachers completed training evaluations to assess quality and utility of training and to assess technological proficiencies, attitudes, and use.

Instructors. LINKS Faculty participants included individuals from the following disciplines: Biology, Chemistry and Physics, Family Sciences, Health Studies, Kinesiology, Performing Arts, Philosophy and Psychology, Reading, Teacher Education, and Visual Arts. Two primary training goals existed: (a) Introduction of the LINKS standards and resources, and (b) support for instructor delivery of web-based courses as models for the future teachers in their classes. In collaboration with the Distance Education Learning Team, the goals were implemented through a series of technology-training sessions divided into two categories a whole-group professional development sessions geared to broad topics, and hands-on professional development sessions specializing in specific areas for remediation or advanced work.

Institutionalization Efforts

Throughout the course of this three-year project progress and outcomes for all participants in each of the three populations was continually tracked. The significant proficiency gains in computer use and skills as well as progress in the levels of use by participants provided the necessary documentation to prompt change within the organization paving the way for institutionalization of the project. These institutionalization efforts can be found in the curriculum changes and institutional support provided to faculty.

Curriculum Changes. Based on the success of the LINKS program, integrated approach to technology course requirement is now required for all undergraduate students earning their foundation certifications. The two new undergraduate technology courses are completed concurrently with other new professional preparation courses provided in the first and second semester of the undergraduate teacher education sequence. Working in collaboration with the College of Arts and Sciences as well as the School of Library Information Sciences, the integrated technology teacher education courses are preceded by two specific courses designed to aid in the developmental process of the preservice teacher in relationship to technology skill development. These courses provide the student with a beginning foundation for technology use in the classroom as well as the opportunity to develop information literacy skills.

Institutional Support. The significant cost-share provided by the University has resulted in the establishment of appropriate instructional delivery centers in seven of the largest classrooms in the building housing the College of Professional Education. Specific administrative support has been demonstrated through the acquisition of personnel positions designed to replace the personnel efforts of those in the LINKS center. Additionally, matching funds have been given to support the various training opportunities offered to the faculty. An excellent example of this support can be found in the impetus and support provided for the development of the Post Baccalaureate program to include the use and integration of technology into the curriculum. This focus includes a unique mentoring program between faculty from Departments of Teacher Education and Reading and the School of Library and Information Sciences. This type of approach builds collaborative and lasting relationships among the faculty, a necessary element for the learning process to continue. The new instructional equipment, the new curriculum, and the increased proficiency of our faculty provide an important triangle for effective institutionalization.

Educational Importance

Integrating technology into the preservice classroom in a contextual way positively affects students' attitudes towards technology. Additionally, preservice teachers taught in this type of classroom have increased overall confidence in their technological abilities as well as in their ability to integrate technology into their own classroom (Abbott & Faris, 2000). The amount of knowledge a teacher has about technology influences the extent to which he/she uses technology. Exposing preservice teachers to technologically rich teacher education programs can cause changes in attitudes and uses through experience and instruction (Levinson & Surrat, 2000). These attitudes are especially important when considering their comfort level with specific computer technologies or when analyzing their future plans for technology in their classroom. As technology continues to evolve, it becomes increasingly important to continue innovative programs such as this in order to maintain quality of the instruction offered to the preservice teacher.

Could We Smell the Cooking over the Internet? An Interactive E-Learning Solution for Home Economics Using Synchronized Multimedia

Simon So and Theresa Lai
Department of Information and Applied Technology
Hong Kong Institute of Education
10 Lo Ping Road, Tai Po, N.T.
Hong Kong SAR, China
E-mail: {swwso, tlai}@ied.edu.hk

Abstract: Many cooking demonstrations using videos allow only a linear playback of the process and are not effective for learning and teaching. In this paper, we demonstrate an interactive e-learning solution for cooking using synchronized multimedia techniques. Textual information and context-sensitive hyperlinks are timely displayed alongside with videos. Students can easily jump into any segment of the demonstrations to re-enforce the concepts and steps. Advanced features in Synchronized Multimedia Integration Language (SMIL 2.0) such as clickable video hot-spots, overlapping multimedia regions, streaming and media objects synchronization are used to enhance the effectiveness of our solution. Surely, we cannot smell the cooking process over the Internet yet, but we can do many other things using an interactive learning environment that hands-on demonstrations cannot do.

Introduction

Scientific understanding of food preparation techniques is an important part for the study of Home Economics. Very often, providing students with the knowledge of recipe development and modification under diverse range of processing conditions require hands-on demonstrations. Demonstration is a very useful instructional method to illustrate procedures and explain new techniques (Chamberlain, 1992). However, a well-executed demonstration demands much time in planning, preparation and skilful manipulation of the demonstrator, yet there are limitation in the learning and teaching processes. Firstly, it must be conducted in continuous action that could not be retaken for slower learners and absentees. Learners within a class are often varied in their abilities. Secondly, some complicated processes should be viewed closely but it may be difficult to provide sufficient space so that everyone will be able to see clearly. Although hands-on demonstrations provide authentic experience to the students and should not be substituted completely, video cases can be used to alleviate some of the problems we face in the Home Economics classes (Stephen and Leavell, 1999). Furthermore, videos open up other dimensions of learning in which conventional demonstrations cannot provide.

In this paper, we explore the effectiveness of using synchronized multimedia to provide an interactive e-learning environment for food preparation in teaching Home Economics. An example of "Chinese dough-making without raising agent" is used to illustrate our concepts. This food preparation technique is very common in making Chinese buns and dumplings. Two illustrative dishes, namely *Steamed Buns* and *Wor-tips* (steamed meat dumplings), will be used to highlight the features of our solution. Our aim is to demonstrate how we can foster an interactive e-learning environment using synchronized multimedia techniques over the Internet (Slowinski and Kennedy 2002; Williamson, 2001). Students can learn at any time and any place using streaming technology (Alesso, 2000).

Overviews of our E-Learning Environment

Our E-Learning solution is composed of the popular three-pane environment with the metaphor of "play/more/explore" (RealNetwork 2002). Figure 1 illustrates our three-pane environment. On the left is the media playback pane. On the right is the related information pane. On the bottom is the media links pane.

Figure 1. Three-pane Environment

Chinese Dough-making Without Raising Agent

In preparing the dough, we show the ingredients for the Chinese dough as in Figure 1. The media playback pane displays the video clip of the ingredients. The teaching points associated with the ingredients are timely outlined in the related information pane. Additional links on teaching notes, materials, and URLs are click-able for further exploration as shown in Figure 3. Please note that the media playback provides subtitles in addition to the audio in the video clips. This feature is effective for learning (i.e. the dual coding / modality principle). Users can control the synchronized materials by pausing, playing and sliding the controls to skip, revisit and hold the materials at any time.

Ingredients for Making Chinese Dough

60g	plain flour
1 tsp	lard
pinch	salt
2-2.5 Tbsp	hot water

Important Points.

1. Plain wheat flour is usually used.

2. Fat is to improve flavour and keep the quality of dough. Lard gives best flavour and vegetable fat (e.g. Crisco) provides a cholesterol-free alternative, however, solid vegetable fats contain unsaturated fatty-acids.

Figure 2. A snapshot for playing the video clip of the ingredients

Illustrative Dish (Steamed Buns)

In the illustration of making steamed buns, we demonstrate the effective use of multiple overlapping multimedia regions for e-learning. Very often, we need to stream media clips to different regions of the screen to show the time relationship and/or the spatial composition of the media clips. In Figure 4, we demonstrate the use of overlapping regions. When a static picture of the ginger juice is displayed in front of the overall picture of ingredients, a short video clip for the preparation is shown in an overlapping region. This stimulates the video feature of "picture-in-picture" in overlapping regions.

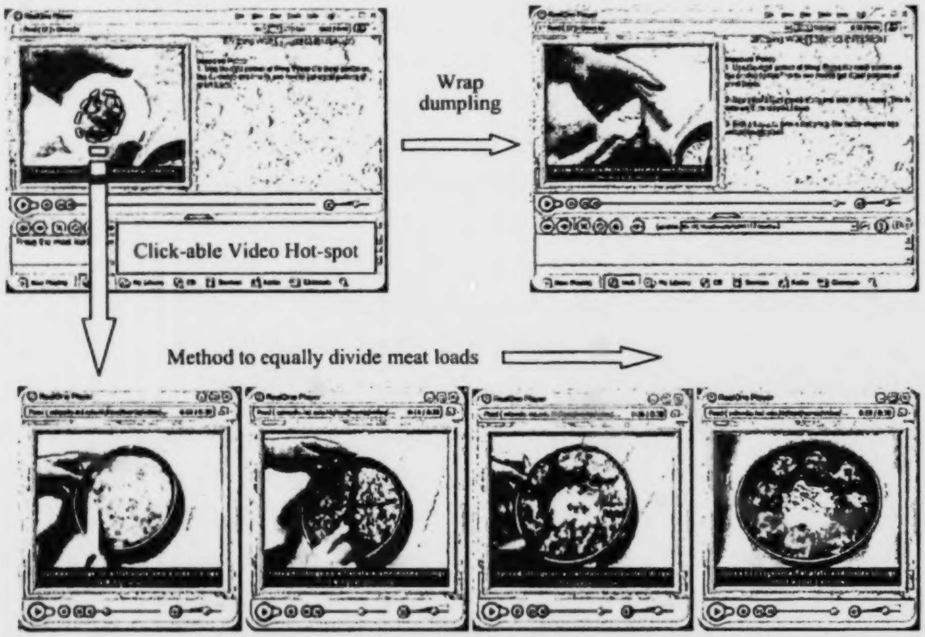
Illustrative Dish (Wor-tips)

In the illustration of making Wor-tips (meat dumplings), we choose the advanced feature of click-able video hot-spots to demonstrate the high-level of interaction that the synchronized multimedia can provide. During the preparation process, the irregular shape of the meat load is used to form a polygon of a click-able video area. Users can click the polygonal region to bring up the demonstration on how to prepare an equal portion of the meat load in Figure 6. This kind of interaction is powerful for e-learning. Users can directly obtain the relevant and timely information visually.



Wrap dumpling
Click-able Video Hot-spot
Method to equally divide meat loads

Figure 6. Illustration of click-able video hot-spot on wrapping wor-tips

Conclusive Remarks

In this paper, an interactive e-learning solution for the study of Home Economics is provided. The effectiveness of using synchronized multimedia techniques for e-learning is highlighted. Students can interactively learn the food preparation at any time and any place over the Internet. It opens up many possibilities that traditional hands-on demonstrations cannot do.

LessonML: A Markup Language to Facilitate the Exchange and Presentation of Lesson Plans

Simon So
Department of Information and Applied Technology
Hong Kong Institute of Education
10 Lo Ping Road, Tai Po, N.T.
Hong Kong SAR, China
E-mail: swwso@ied.edu.hk

Abstract: In the Hong Kong Institute of Education (abbr. HKIEd), a vast amount of lesson plans for primary and secondary teaching practices are prepared by our pre-service teachers. These valuable documents are being wasted each year. One reason for this is that there are lack of formal mechanism to keep them. The other reason is that the non-standardization of these electronic documents prevents an effective exchange and retrieval of their contents. In this paper, a formal markup language for lesson plans is proposed and developed using XML. The formalization for the various components of lesson plans helps to foster a non-ambiguous data model. Using XML technology, not only we can relevantly query the lesson plans, we can display their contents in a variety of formats and styles using web-based technologies such as XSL and XSLT.

Introduction

In HKIEd, pre-service teachers are required to conduct teaching practices at their attached schools. They are normally assigned to teach their major and minor subjects so that they can gain teaching experience relevant to their subject knowledge. Among the various teaching activities they perform, they must prepare a series of lesson plans for their assigned periods. Their lesson plans are mostly in the form of typed and/or hand-written documents. After completed their field experience, there is no mechanism for them to systematically store and share them within this organization. These valuable lesson plans in large quantities are being wasted every year. However, if we can provide them with a markup language similar to SGML or HTML, they can prepare their lesson plans using the defined language. The advantages of using a standardized markup language to compose lesson plans are the following:

1. Self-description in tags such as <Teacher>, <Topic>, and <Motivation> can be established;
2. Highly structured information can be stored;
3. Searching can be more accurately;
4. Lesson plans can be easily displayed with different styles and formats; and
5. Interchange of lesson plans between organizations can be easily achieved.

In this paper, the proposed markup language is fully described with an example to illustrate the power and expressiveness of this development. One application of the markup language is also shown.

Language Overviews

There are many formats for lesson plans in the education community (AskEric, 2002; Leeck, 2002; LessonPlansPage, 2002). In HKIEd, a typical format of a lesson plan (Pang, 1992) is illustrated in Figure 1. The *learning objectives* section and the four teaching sequences namely *introduction, motivation, development and consolidation* are the essential components for our lesson plan. Some sections such as the *blackboard arrangement* section are optional. To define LessonML, we use XML DTD (Document Type Definition) to provide *validity* constraints (Buyens, 2000; Hunter, 2000; Wyke, Rehman & Leupen, 2002; Young, 2000) for our language[1] as shown in Figure 2.

---

[1] XML Schema is a better choice to define the structure, but we will use DTD to design LessonML.

Figure 2. LessonML

XML Attritudes are deliberately avoided in our language to cater for a variety of applications. Furthermore, the design is not only relevant to the HKIEd's environment, the language is very suitable for the general public as the cardinality operators for the elements are specially considered. To illustrate this, a very brief lesson plan with minimal tags for teaching "Electronic Mail" is shown below:

```

LessonML Applications

The language provides a framework for lesson plans to be used in many applications. One obvious application is to generate Web pages for the structured lesson plans. By separating the data model and the display format, one can have a number of styles and different content emphases. Figure 3 shows a particular design for displaying the content of the above lesson plan using XSL technology.

Conclusion and Future Work

The proposed markup language facilitates a standardized framework to represent and exchange lesson plans among applications. The structured data model provides a formal mechanism for our students to effectively store and retrieve lesson plans.

Currently, a small project is undertaking to organize lesson plans in HKIEd. The markup language described in this paper provides an important foundation to the project. Lastly, like many standards and languages, LessonML will be expanded continuously to enhance its elements.

Designing Attractive Virtual Spaces for E-Learning

Marion R Finley, Jr., Yuki Sogabe
Multimedia Laboratory
Asahi University
Hozumi-cho, Gifu Prefecture
501-02, Japan
{finley, ysogabe}@alice.asahi-u.ac.jp

Abstract: The work in progress described in this paper extends previously reported work on the construction and testing of virtual communications spaces for use in creating *attractive* Internet/Web-based environments, that is, virtual spaces, for e-learning. Such spaces, or, more precisely, the underlying Internet/Web-based systems that support these spaces, are related to human factors via utility functions, such as "willingness-to-pay," "user satisfaction," and the like. These functions are functions of internal system parameters. Optimal values of such functions then would correspond to "attractive" virtual spaces. An M^2COTS ("mass-market components off-the-shelf") approach is adopted. A formal characterization is given which will allow precise definitions of experiments to be performed to determine criteria for the construction of such spaces.

Introduction and Objectives

The basic *leitmotif* of the work being conducted by the authors is to determine a set of operational criteria for the design of Internet/Web-based virtual spaces that will be both "attractive" as well as "effective." This work extends work previously reported by the authors (Sogabe *et al* 2000). The keywords, "attractive" and "virtual space" have rather precise and limited meanings that will be given in some detail in this paper. Intuitively, however, they refer to a kind of environment, a specialised cyberspace or virtual reality (Beier 2000, Jensen 1999, Webopedia) one might say, created by computers, peripherals, and networks, that appeals to the intended users to the extent that the latter will be attracted to it and be willing to pay for access to it. These spaces are being applied initially to create e-learning environments to be used in graduate and undergraduate education in Japan (Finley 1999). The implications of the terms "attractive" and "effective" are simply that, for the first, the spaces must attract and hold the attention of the targeted users, in this case, potential graduate and undergraduate students in Japan, and, for the second, that they will achieve economic and pedagogical goals set by the institution, that is, they will be "effective" in realizing such goals. To simplify the terminology, in this paper the term "attractive" will be used to include the implications of both of these terms and, by extension, they will be applied to the e-learning system as a whole. In the work performed so far, the emphasis has been less on course content per se as opposed to the system infrastructures (Fernandez *et al* 2001) that render the virtual spaces produced "attractive." Therefore, at this phase of this work, courseware as such is not the immediate object of concern. In the work reported here, continuing the approach of previously reported work, an M^2COTS (Mass Market Components Off-the-Shelf) approach (Sterling *et al* 1999) to the design of experimental e-learning systems is being followed as much as is possible, therefore essentially restricting the designers to the use of to readily available and affordable off-the-shelf hardware and software. An initial definition of "attractive virtual space" has been given in previously reported work and is refined and extended in this paper. This definition appeals to the concept of topological spaces over which a utility measure (Deardorff 2001) is defined that relates internal system parameters to human-oriented parameters, for example, "willingness-to-pay" (Akimaru *et al* 1999, Yamori 1999) as a function of such system parameters as line bitrate, the various characteristics of display devices, etc. Optimizing a utility function yields an attractive space, using as criterion for "attractive" an optimal value of the function. Such a utility function may be constructed experimentally using human subjects and studying their reactions, for example, by carefully formulated questionnaires. The resulting functions may then optimized by using methods such as genetic algorithms Goldberg (1989) or others that are suitable for such cases, that is, functions of several variables whose optimum values may be difficult to obtain by the usual optimization techniques. The UML (unified modeling language) (Page-Jones 2000) is used to express the system architecture: hence the basic approach to the design is object-oriented.

The underlying intention of the authors' work is to attack a fundamental vexatious issue plaguing the computer and telecommunications field; namely, how to predict the intended customers' acceptance of a new telecommunications service or a new computer or telecommunications product. E-learning forms a special category of computer and telecommunications systems, one that, in the authors' opinion, merits careful study as far as the design of the environment ("space") which the students and professors of the future must inhabit for learning and teaching. If the authors are successful in their effort, they will be able to offer specific design criteria to e-learning designers that will render the resulting environments "attractive."

"Attractive" Virtual Spaces

The term virtual space has seen many uses and the authors have been influenced by such as (Fernandez *et al* 2001) and (Jensen 1999). For the moment, a virtual space, ***V***, will be informally characterized as a quadruple consisting of a collection of objects, ***O***, a collection of points, ***P***, a topological space, ***T***, over these points, and a metric, ***m***, over T. ***R*** is a set of *protocols* relating the objects among themselves. These are, in the terminology of the Open Systems Interconnection (OSI) reference model, application layer protocols. That is, $V = \{O, P, T, R, m\}$. The objects are primitives that will be associated with the points, or collections of points, of the topological space. As examples of points, one might consider such things as URL's, IP addresses, MAC addresses, etc. Objects may be pieces of equipment, human users, or software constructs. Generally, objects will be defined using a language such as the UML (Unified Modelling Language) (Page-Jones 2000). Compound objects will be sets of objects with specified relations between the objects. A topology is essentially a connection diagram relating points and objects to each other. A metric will be some measure over the elements of this connection diagram, for example, the total packet delay between two points. That is, in a virtual space, the concept of distance is related to the passage of time, and not necessarily of geometrical distance. Of course, ***m*** may be a function whose independent variables include time and geometric distance measures. The *dimensionality* of a virtual space implies at least the four dimensions of space-time and perhaps other dimensions as well, for examples, dimensions that include human behaviour. This is a complex issue and will not be considered further in this paper. The *specification* of a virtual space, ***V***, may be made a various levels of granularity, depending upon the aspects of the space upon which one wishes to concentrate. For present purposes, the emphasis is at a coarse level. It should be noticed that this characterization of virtual space does not specifically isolate real-world external objects, for example, the human users or physical devices, from objects that are software constructs, for example, avatars or other objects displayed on the user's screen. Moreover, some objects may span the external real-world and the world of software constructs, for example, the blending of some physically displayed object with objects in the physical environment. Rather, what counts is, that, in an object-oriented fashion, every object of the space will be characterized by a set of attributes and behaviours. Therefore, the frontier between what exists in the external real world and what exists solely in the system becomes blurred and now "reality" entails objects and relationships that exist in a man-made system ... and in the mind of the user. A virtual space, however, is supported by a multimedia communications system infrastructure as well as physical objects such as rooms, chairs, etc. While the specification of a virtual space may not explicitly define these objects, yet they can be included at a higher level of granularity. In this work, we shall be interested in the relationships between certain key internal system parameters and some aspects of human behaviour and shall content ourselves with just enough granularity to cover these.

In industry, the term *human factors* refers to aspects of human behaviour, both physical and psychological, that relate to particular environments, products, or services. The word *ergonomics* is used in the same sense. There is the specific implication that human factors may be reduced to measurable quantities. Human factors are used to study the possible acceptance of a new product or service by the targeted users or consumers. Human factors studies play a crucial role in the development of new products or services and help determine how human beings react to the technical aspects of these products as well as to new types of products and services.

In the present study, the purpose is to identify those human factors that determine the level of attractiveness of a given virtual space and then to relate these factors to key parameters of the virtual space. This may be done by using a kind of objective function termed *utility function* (Deardorff 2001). In economics, these are functions that specify the *utility* (well being) of a consumer for all combinations of goods consumed (and sometimes other considerations). Such functions capture critical aspects of the consumer's attitudes towards the goods being proposed to him. In this work, they will capture attitudes towards new proposed telecommunications products or services. Examples of utility include *willingness-to-pay*, *user satisfaction*, and so on (Webopedia). Such utlities may then be related to key parameters of the virtual spaces being considered, for example, screen definition, transmission delays, and so on.

As for the concept of "attractive," this, of course, intuitively simply means "capable of attracting, intriguing, and holding the interest of members of a target population," in the case of the authors' work, the potential candidates for using the e-learning services they are developing. Attractive virtual spaces in the context of e-learning would then tend to attract and maintain interest in the target student population. Utility functions may be used to measure the attractiveness of a given virtual space. Using skillfully designed questionnaires to poll users attitudes as function of key system parameters, as indicated above, one may identify the factors that make a virtual space attractive to the intended users and build empirically the corresponding utility functions. More precisely, results of the polling will give values of the utility as function of the system parameters of interest. Then, by using standard curve-fitting techniques, one may derive functions for the utility. Optimal values of these functions may then be obtained by optimization techniques such as genetic algorithms (Goldberg 1989). If $\mathbf{u} = \mathbf{u}(\mathbf{p}_1, \ldots, \mathbf{p}_n)$ is a utility function of parameters $\mathbf{p}_1, \ldots, \mathbf{p}_n$ where the $\mathbf{p}_i$ are the critical parameters of interest for a given virtual space *V*, then we say that *V* is *attractive with respect to the* p_i *of a given utility u* if, for values $\mathbf{v}_0, \ldots, \mathbf{v}_n$, $\mathbf{u}(\mathbf{v}_0, \ldots, \mathbf{v}_n)$ is a maximal value of **u**. The word *maximal* is used here rather loosely to mean a relative maximum that will satisfy the needs of the modeler at the moment. Since **u** may be an ill-behaved function for maximization purposes, in practice a relative maximum may be sufficient and such a relative maximum will be called a maximal value. The concept of attractive virtual space then is defined relative to some form of utility and some system parameters. This corresponds to our intuitive idea of the concept "attractive" as being a subjective evaluation according to various criteria. In the case of human beings, these criteria often are difficult to render explicit, hence the need for human factors studies as mentioned above.

Design and Testing of Attractive Virtual Spaces

With the aid of the concepts and mechanisms presented on the previous sections, the strategy of the authors then is to attempt to build experimental virtual spaces, subject these to testing with human participants, study their reactions using various polling and interviewing techniques, then attempt to derive meaningful utility measures. The latter then will be used as a basis for further development and experimentation. Thus, there will be an alternation between experimental work on the one hand and theoretical developments on the other. A crucial matter is the specification of the set of protocols ***R*** mentioned above in the definition of *V*.

In the conceptualization of that which constitutes *attractive*, the seminal work of (Norman 1990), and (Shneiderman 1998) are being found in the search for the qualities that might render an object, here a virtual space, attractive. At this time, these and related work and ideas are being explored in the quest to derive meaningful criteria for attractiveness as well as to find viable utility functions. Up to this point, attractiveness criteria have been sought by strictly intuitive reasoning, which, all the same, has proven to be effective in the design of several experimental virtual spaces in the context of tele-learning. These spaces were used in several trials in real classroom situations. In these initial trials, as previously reported (Sogabe et al 2000), initial results were very encouraging, but the formalism developed above was not yet available and no formal utility functions were used.

Conclusions

A crucial step in the process of attempting to find practical design criteria for attractive virtual spaces has been taken. Namely, it is now possible to characterize exactly what is meant by such spaces for a given application. This, in turn, leads to a precise way of defining meaningful experiments with such spaces and real human subjects. This in turn will allow the building of relevant utility functions and the optimization of the latter. The optimized results will then yield, for the given application, an "attractive" space or communications environment.

Web based Training on Radiographic Testing

ABSTRACT

The purpose of the creation research were to construct the Web Based Training on Radiograph Testing, to evaluate the package efficiency and to determine the students achievement of gaining by using this package.

Thirty students participated in the experiment. These students were the second year of Production Engineer from King Mongkut's University of Technology Thonburi. Prestest and posttest were conducted.

The research found that the Web Based Training had the efficiency of 83.86/85.64 which was slightly above criteria 80/80. The comparison between pretest and posttest performance of student was statistically significant different at 0.01 level. This result of comparison indicated the Web Based Training on Radiograph Testing, was enable learner gaining high achievement.

1. Introduction

In some ways, there are many types of learning system such as class conduction learning which is conducted by teacher, self-learning from various type of mediums, printed matter, video, for instances. But nowadays computer communication technology has become one of an important implement in teaching. In order to assist instructor and, in some cases, to be in place of teacher, the technology has been applied in teaching system by construction lesson in form of CD-ROM. Although the CD-ROM lesson is very beneficial to the learners but there are still some limitations to learners because learning through CD-ROM is not suitable for group participants.

In order to eradicate the problem, project constructors have applied the advanced computer technology, which is well-known called Internet, into the computer assisted instruction system. In this development respect, learners are able to study the constructed lesson pleasurably either studying individually or in group participants. Due to the advantage is the constructed lesson is written to perform on website that means if there is a computer connected to the internet system, learners can study the lesson throughout.

Reasoning to Radiographic Testing subject has never been written its web based context before, so that project constructors have chosen the subject to construct its web based context. In this respect, the project constructors have bore the fundamental of Interactive Multi-Media Computer Assisted Instruction (IMMCAI) system as its principle.

2. Objective

1. To construct a web based computer assisted instruction for Radiographic Testing subject.
2. To increase learning efficiency to the Radiographic Testing subject.
3. To examine the lesson effectiveness and the learner's learning efficiency.

3. Expected Benefit

3.1 For learning : learners can study the lesson at any time, any where as they see fit.
3.2 For teaching :
    3.2.1 To decrease time consuming in tools preparation.
    3.2.2 To be a learner-center instruction lesson.
    3.2.3 To be a web based e-learning instruction.

4. Project Hypothesis

4.1 The constructed web based computer assisted instruction bear effective standard at 80/80.

4.2 The constructed web based computer assisted instruction provides more learning efficiency to the learners.

5. Research Direction

- People and Group of Samplers

1. People : Students of bachelor degree level of the Engineering Faculty of Engineering Department of Production Engineering who had registered to take class of Radiographic Testing subject.
2. Group of Samplers : Students of bachelor degree level of the Engineering Faculty of Engineering Department of Production Engineering who had registered to take class of Radiographic Testing subject. The group had been divided into sub-groups as follows :-

2.1 The group for evaluation the effectiveness of the test. The group consisted of 30 students for evaluation the certainty and easy-and-difficulty of the tests.

2.2 The group for evaluation the effectiveness and efficiency of the lesson. The group consisted of 30 students.

- Tools of The Studying

1. Computer assisted instruction of Radiographic Testing subject.

2. Regular tests of the subjected credit and regular lessons test which were 4 choices tests. The tests were consisted of 300 questions and were divided into 3 sections which were pre-study test, interval-study test and finished-study test.

- Evaluation of lesson effectiveness and efficiency of learning

Evaluated with group of samplers who were 9 of the sophomore of the students of the Engineering Faculty of Engineering Department of Production Engineering and never studied the Radiographic Testing subject prior to the test. The test had been carried out step by step as stated below.

Step 1. Pre-study test was for recording points prior to studying the subject for making evaluation.

Step 2. Interval-study test was to evaluate the learners.

Step 3. Evaluate the learners after finishing the study.

- Data Examination

Divided the interval-study testing points and finished-study testing points into percentile. Then, compared the percentile with the average standard to find an acceptable result. The standard was set at 80/80. The result revealed details as follows:

1. The result of learning effectiveness

Based on non-relation of the group of samplers, by testing to find t-test point, the result of assumption of the 2 different groups of points averages and the points were pre-study test points and finished-study test point, the result after examination demonstrated that average of finished-study test points was 258.00 which was higher than the average of pre-study test points which was 80.78. It apparently reveals that the constructed computer assisted instruction accomplishes more knowledge to the learners.

2. Result of Field Testing

The test was experimented with 30 students who never studied the Radiographic Testing subject prior to the test. The result revealed the learning effectiveness was at 83.86 per cent and the lesson effectiveness of changing student's behavior was at 85.64 per cent. Therefore, the effectiveness of the lesson was 83.86/85.64 which is significantly higher than the standard.

6. Summary

The study shown that the constructed computer assisted instruction possesses higher effectiveness that the standard. In order to strengthen the difference, t-test had been carried out. The result of t-test revealed that the difference was so important as of statistically meaning at 0.01. Conclusively, the constructed computer assisted instruction makes more compressive effectiveness learning to the learners. And it can be a tool to educate general people who are interested in the Radiographic Testing subject.

7. Revelation

Because of bearing the 16 steps of the principle of IMMCAI, and the property of the constructed web based lesson is multimedia system, it makes the construction of computer assisted instruction for the Radiographic Testing subject brings more effectiveness and efficiency to learning of the relevant subject. And it is the web based lesson that makes an interesting interactive with the learners. Moreover the lesson provides a choice in choosing to learn individually or in group participants because it performs on website which no specific time learning requirement.

Multimode Virtual Consulting (MVC) Environment as an Alternative to Faculty Office Hours: A Work-in-Progress Report

Peter Soreanu
Department of Software Engineering
ORT Braude Engineering College
Karmiel, Israel
speter@actcom.co.il

Abstract: This paper is a preliminary report of a work-in-progress study. The research was done on the use of asynchronous and synchronous internet-based tools as a virtual academic consulting environment. Only partial qualitative results were obtained and they are presented in the paper. The main results confirm that there is a need for more than one tool and that the most efficient synchronous and semi-synchronous sessions are those that are well structured. Rigorous statistical analysis will be done at the end of the study, after continuing the experiment for two more semesters.

Introduction

The paper reports the preliminary results of an ongoing research on the use of virtual environments as tools that support students during the course delivery. The target population consists of more than 120 third year Software Engineering students. Their previous computer-related experience is expected to significantly reduce the novelty effect on their behavior. The research will span over a 3-semester period. The presented results were obtained after the first semester.

The course delivered in the first semester is an introductory course in Computer Networks. It is an in-person attendance required course, not intended for remote electronic delivery in an e-learning environment. The course is, however, well supported by Web-based materials: slides, short notes, video on demand, review questions, glossary, automatic assignments checker and more. It will be followed by 2 more courses on advanced networking topics. For every aforementioned activity, professional advice and administrative support is required. During the experiment, the existing office hours were not suspended or reduced, but merely supplemented by several virtual communication and/or collaborative tools.

Technologies Involved

The MVC environment comprised the following tools: forum, e-mail, virtual briefcase, Web-based conferencing. Such settings and their educational use are extensively described in (Wolz et al. 1997).

The forum was intended primarily as a discussion environment, facilitating communication among students, but also with daily monitoring and active participation of the teacher. It is tightly integrated with the course delivery, being an important part of the Virtual Classroom (Hiltz & Wellman 1997). The sporadic utilization of the forum for not course-connected matters was tolerated, but not stimulated. Students not only asked questions and raised problems, but also posted recommended relevant links that they thought would help others. The access to the forum was restricted to students who took the course.

The use of e-mail (see Khrishnamurthi 1999) was confined mostly to personal questions posed by students. The teacher also used e-mail for feedback on assignments, on his own initiative. There were occasions when a question posted publicly in the forum was answered directly by e-mail, according to the teacher's decision.

A virtual Web-based briefcase was also opened, to facilitate the collaborative work between students. The teacher didn't participate, but the students' activities there were monitored.

In order to add tools that permit more complex interactions, a synchronous Web-based conferencing system was also set up. The software is described at http://www.interwise.com.

Custom software was also developed for the experiment's purpose, permitting to associate students' name with their thumbnail photography and other personal data. This add-on feature contributed to a more personalized approach while interacting with the students. Special care was dedicated to the computer-human interface (Soreanu 1998)

Research's Aim

The research's goal was to study the comparative use of those tools, related to their adequacy for various tasks. Ultimately, they would result in recommendations to other faculty, concerning the most suitable environment. The expected results were based on an extension of Spiro's Cognitive Flexibility Learning Theory (see Spiro, Coulson, Feltovich & Anderson, 1988; Spiro, Feltovich, Jacobson & Coulson, 1992; Jacobson & Spiro, 1995) to what we defined as an MVC environment.

The first hypothesis: Solutions to complex tasks are correlated with the number of used communication tools.

The second hypothesis: The complexity of the task to be resolved is proportional to the sum of the complexity of each tool.

The third hypothesis: The use of the MVC environment is correlated with a positive change of attitude of the students toward themselves and the teacher.

Research Methodology

The tools utilized for the research were questionnaires, interviews and observation. The person-to-person contacts between teacher and students in this period were also logged and possible correlations investigated. The students were explicitly asked to use the MVC extensively, but that was not one of the course's requirements.

The forum was used in two distinct ways. The first is a non-moderated environment, where the threads were proposed by students and the teacher merely intervened to clarify recitation and homework issues. The forum was also used as a semi-synchronous tool, with the teacher present at previously announced hours. Those hours were posted periodically, and changed according to schedule constraint and students need. The frequency of these semi-synchronous sessions was increased during examination preparation periods.

The later use of the forum was decidedly a structured one. Although this use was quite widely researched recently (see Farnham et al. 2000; Churchill et al. 2000; Thirunarayanan & Perez-Prado 2001), we felt that more investigation is needed to better explore this path.

For the Web-based conferencing, we used only the structured approach, i.e. the subject was announced in due time and was of interest to most of the students. The teacher used PowerPoint slides from the course recitation combined with graphic tablet and audio input. The students used text and audio input. In order to reduce the bandwidth requirements, no video was allowed. The environment permitted object and application sharing.

The e-mails were analyzed according to the content.

The virtual Web-based briefcase was used by students to interchange documents. A singular attempt to use it for homework cheating was promptly rebuked.

We logged and analyzed the utilization patterns of students when using the MVC. For the conferencing system, we also identified an important group of inactive participants, the "lurkers" (see Nonnecke & Preece 2000).

We classified the complexity of the problems according to Bloom's taxonomy for categorizing the level of abstraction of problems that students rose when using the MVC. We classified each of the Multiple Choice Questions that the students were asked to answer. We used for this purpose a methodology elaborated at Cape Town University, South Africa (see http://www.uct.ac.za/projects/cbe/mcqman/mcqappc.html). We classified all the problems and questions that occurred while using the MVC, including organizational ones.

To check the user satisfaction, we used a paper and pencil questionnaire. For this purpose, an attitude instrument was developed, using a Likert scale. We applied the Cronbach's Alpha Reliability and obtained alpha = 82.

These results were corroborated with the communication pattern among the students.

Preliminary Findings

After using the devised MVC for one semester only, we have not gathered enough data to unequivocally confirm/reject the first two hypotheses. The results seem, however, to support them. We will continue the experiment for two more semesters, with the same students and teacher.

However, we have drawn some preliminary conclusions about the use of MVC, the research methodology and user satisfaction.

All tools were used quite intensively and have their place in the MVC environment. We have found that the best use for the semi-synchronous sessions is to support self-learning assignments that are required items for the final exam. In this case, the user participation was very high, most of the students were active and the subsequently administrated user satisfaction questionnaire confirmed the usefulness of the session.

The most valued use of the conferencing system was its use for 6 consecutive days before the term examination. As expected, the lack of video channel was not resented and the audio media (see Ackerman et al. 1997) was preferred vs. the textual one. There were a few technical problems, as connecting the microphone or downloading the slides. Their number was low and the students solved them relatively quickly. An interesting pattern emerged, groups of 34 students participating from the same computer. Having them using the same username was quite confusing and we work to upgrade the custom software containing their photos and data to allow for *ad hoc* grouping.

Anyway, the most successful on-line sessions were those that were well structured, dedicated mostly to a single subject and supported by additional course data.

The next stage of the study will further refine the research methodology. Aspects that yielded no significant results in the first semester will be investigated from a new perspective. Task vs. tools matching will also be studied.

The used MVC environment will continue to be used as an experimental test bed for virtual teacher-students interactions intended for academic consulting purposes.

LABORARY©: a Library of Lab Set-ups

Hugo Bohets, Tor-Björn Johansson, Herbert Peremans, Karel Soudan, Laurent Van Haverbeke
Faculty of Applied Economic Science UFSIA-RUCA
University of Antwerp
Belgium
Karel.Soudan@ua.ac.be

Abstract: The LABORARY© concept is designed to allow students to perform real experiments at any given time in a similar way students consult books in a library. For this, lab-instructions and material are configured to give both free access and autonomous use, while students are released from tedious and distracting tasks. The concept is demonstrated by case studies in Chemistry and Electromagnetism in which all three pillars of autonomous real labs have been successfully applied: 1) Intuitive user-lab interface, 2) interactive and bi-directional guidance, 3) Emphasised focus on main topic. Success results are shown by student questionnaire. Further developments will include both local and remote real lab exercises in the overall concept.

Introduction

Laboratory classes have become a necessary part in the teaching of science and technology as real life experiments and demonstrations provide a great enhancement of the understanding of theoretically discussed topics. While the expenses to install and operate these laboratory classes represent a growing part of the available funds for educational activities the achieved educational benefits of traditional lab classes are however sometimes very poor. The reason for this must be found in the way a traditional lab is configured: the same type of experiment has often to be carried out by a relatively large group of students at the same moment. The students are then forced to carry out experiments they may not be interested in, at time slots that may not fit into their individual work scheme. In many cases, they come to the laboratory uninterested and poorly prepared and they carry out the experiment solely by following the recipe. The pursued goal of aiding them to understand the underlying theoretical principles can hardly be achieved in this situation.

Developments in electronic media offer an opportunity to perform this task through the integrated use of telecommunication, network technology and multimedia computer systems. Computer-assisted multi-medial instruction is generally accepted as the preferred platform for individualised instruction: repetitive tasks can be partly taken over from supervising personnel, allowing them to perform more creative tasks and to tailor their activities to more dedicated assistance to the students. On top of this, knowledge and teaching aids can be shared through networking, telecommunication and teleconferencing, allowing a more widespread use of the existing means.

LABORARY©

By using electronic media the LABORARY© concept helps to find adequate solutions for the above problems of traditional laboratory education. The LABORARY© is seen as a laboratory that can function in the same way as a library. A relatively large number of different lab set-ups is available to the students to be consulted if the experiment is not being carried out by someone else, at any time slot they choose within reasonable working hours, in fact in a similar way students consult a book or a CD in a library.

A student or a team of students selects from the list of available labs, associated with the course he is attending, which one(s) he or she is interested in, and looks for a time slot that fits into his personal schedule to carry out the experiment. At the chosen time slot, he checks into the LABORARY©, carries out the experiment and makes up the lab report to be delivered within the indicated deadline. Because the student has to take the initiative to choose both the kind of experiment and the time slot to carry it out, he is much more involved in the experiment. Enquiries with the students and analysis of the lab reports indeed show that they are much more interested in the experiment and that they obtained a much deeper insight in the underlying theory of the experiment.

On top of this the whole or at least part of the laboratory work can be done on a distance by proper use of communication technology integrated in the lab set-ups, creating a proper environment for real remote lab exercises.

Library of real lab set-ups

To function properly, the LABORARY© must contain autonomously consultable lab set-ups, which means that the experiment itself can be carried out with virtually no interaction from teaching assistants. Repetitive tasks can be taken over from supervising personnel, allowing them to focus more on insight discussions.

Using a combination of a multimedia PC, LabVIEW™ and internet-like interfaces, computer controlled lab set-ups were created in which students are both monitored and guided by the interface software. Figure 1 to 4 illustrate the several parts ('pages') of a typical LABORARY© exercise:

- In a login page students identify themselves as individuals or by group.
- A second page informs about the current lab exercise and guides the student through the related expected prior knowledge and the theory that is to be explored in the experiment. The student may be prompted to a few questions and can only proceed after giving correct answers. (fig.1)
- A third page provides practical instructions on the actual experimental activities and measurements. (fig. 2)
- The next page is handling the real interaction of the actual measurements and the displaying of the results. (fig. 3)
- The last page overviews the results of the experiment, allowing the student to print them or/and transfer them to his own computer account to prepare an individual lab report. (fig. 4)

Discussion and results

Several set-ups - related to chemistry and electromagnetism courses - are already designed in such a way that they incorporate and even stimulate self-learning, creativity and personal initiative of the student. Each experiment goes beyond pure demonstration of the theoretical background concerned and contains an active and/or interactive component and allows creative inputs of the student.

From the development phase following didactic and practical improvements (as compared to the traditional lab approach) can be concluded.

The LABORARY© concept:

- allows the student to choose his/her own pace
- improves the possibilities for the student to repeat parts of the lab exercise which to him/her were less clear
- reduces overhead, i.e. connecting and configuring devices, when these activities are not the purpose of the lab exercise
- improves student involvement through enabling a choice of lab exercises, e.g. 3 out of 5
- stimulates the student to work and solve problems independently
- enables assisting personnel to spend more time on guiding the students in the interpretation process rather then the execution of the lab exercise itself
- makes it possible for students to choose the date and time when they carry out the lab exercise
- improves the maintainability and further development of the lab exercises

From a survey among the participating students we can conclude as follows on the proposed statements in the survey:

- *The information supplied by PC is ample to perform the practical aspects of the experimental set-up*: agreement.
- *I find it necessary that the lab supervisor assists me with the practical aspects of the lab exercise*: limited agreement.
- *I am able to perform these lab exercises in the lab with very limited assistance from the lab supervisor*: satisfying agreement.
- *If the necessary facilities were offered to me, I would consider performing these lab exercises at home*: no clear answer.
- *I find it important to discuss the results with the lab supervisor before I write my lab report*: agreement.
- *From this series of lab exercises I have enlarged my knowledge and understanding*: agreement.

Conclusions for future developments

The combination of LabVIEW™ and multimedia PCs results not only in a cost-efficient and easy to use measurement systems. It also provides a pedagogical sound electronic assistant, provides the possibility to reduce overhead and puts emphasis on the main topic. From the results of the survey its clear that computer assisted lab exercises can work efficiently if a sound experimental set-up is chosen. Furthermore it is shown that the computer interface provides enough information and is easy to use. However there is still a demand for support for the theoretical aspects of the lab.

The ever-increasing possibilities of performing useful activities remotely, in particularly via Internet, suggest that also lab exercises as well could be one of these activities. However, from our survey we conclude that the lack of social interaction discourages students performing their lab exercises from home. A query among students following individual education as distance education might give a different result. Especially since this type of education almost always lacks lab exercises.

Two other important reasons for wanting to perform lab exercises remotely are cost and safety. The possibilities for two institutions to share in the use, and hence the cost, of sophisticated equipment is strongly limited by geographical distance. Remotely executed lab exercises could be an opportunity to share time and hence the cost of such equipment. Ultimately, using appropriate time scheduling, the same set-up can then be used by students from different institutions. If several institutions develop complementary lab exercises based on the same principle, they may end up with an offering of a multiple of the experimental set-ups they have in their own laboratories. Lab exercises that requires toxic or radioactive substances or any other lab exercise with increased hazards as high voltage and high power machinery could also preferably be done remotely. That remotely executed lab exercises would be possible if required is clear from examples as remotely performed surgery.

Abstract: The development of multimedia learning materials is expensive and very time consuming. In spite of these high production costs most materials are reusable only to a very small extent. Project results are often lost in obscurity. This paper demonstrates a cooperative approach of several Austrian universities and polytechnics to produce, configure and reuse multimedia content in the field of Integrated Business Information Systems. A recently founded association called "AKIT" may be used to distribute this content on a nationwide scale.

Introduction

Knowledge concerning "Integrated Business Information Systems" (IBIS) is focused in most computer science studies and spans a variety of topics from the conceptual business process modeling to the implementation details using various Enterprise Resource Planning (ERP) Systems. This knowledge is also currently taught at several universities and polytechnics in Austria focusing on different aspects of IBIS. Learning takes place exclusively in the form of face-to-face courses using individual teaching and learning materials (slides, books, scripts, exercises). Thus far the continuous use of case studies and the connection of background knowledge to such case studies have rarely been practiced in order to understand the universe of discourse. Overtaxing individual teachers' time to prepare sophisticated (multimedia) course materials and the costs of staying up to date with current software versions are the main reasons for this.

A group of university teachers realized this gap and in April 2001 joined an association called *AKIT (Akademische IT Lehr- und Lernplattform*, see also (AKIT)) spanning more than 12 Austrian universities and polytechnics. The main objective of AKIT is to benefit from the synergies available within this network in the teaching process. AKIT members discovered that their teaching objectives in the area of IBIS are mostly similar and they aimed to reuse teaching materials and jointly develop virtual courses based on well prepared case studies. This task, however, could not be achieved immediately. Teaching and learning materials as well as case studies were inhomogeneous, too strongly coupled or demonstrated a lack of continuity. Multimedia materials were not available at all, the way towards virtual classrooms was not feasible.

Having this background five AKIT members, among them universities and polytechnics, designed a project called EduBITE (Educating Business and Information Technologies) to overcome these problems and build up a common repository of multimedia IBIS materials as well as an environment for the customizable usage of these materials in different courses. They chose a situate learning approach focusing on a manufacturing case study enterprise called DeBITE (Demo for Educating Business and Information Technologies). EduBITE started in summer 2002 and has a running time of two years. It is funded by the Austrian Federal Ministry for Education, Science and Culture (bm:bwk).

Project Objectives

EduBITE tries to compensate the deficits mentioned above in the following respects:

- *Teaching Materials:*

Topics relating to 'Integrated Business Information Systems' such as conceptual business engineering, enterprise modeling, the support of business processes implementation or the customization of Enterprise Resource Planning (ERP) systems are prepared for multimedia use based on a case study enterprise (DeBITE). The produced learning modules focus on computer science students as well as business administration students. They cover a four hour/week conventional course in the field of IBIS and will be evaluated over one semester in at least two courses at two different universities or polytechnics.

- *Instruments:*

Instruments are developed to categorize developed materials according to the IEEE international metadata standard. The meta-indexed learning objects can so be used to construct specific lessons according to special target groups or certain learning processes. Instruments for the configuration of course materials using learning process models are also developed. These guarantee adaptation, enhancement and interoperability of the developed multimedia material.

- *Communication Platform:*

The output of the project is aimed to increase the reuse of available multimedia materials in the IBIS context. The AKIT association mentioned above will be the framework to gain access to the multimedia materials and to improve and enhance them. Its members also constitute the market for the sustained use of the project products.

Project Content

EduBITE develops multimedia material using business processes as a basis for the business information system, investigating business process properties, their co-operation on various levels and their technological support. Often students are not able to bridge the gap between complex business processes in reality and the abstract information systems supporting them. But particularly abstraction mechanisms should be comprehensible for students. Using the case study enterprise DeBITE, this process of abstraction should become clearer and more comprehensible, while at the same time making much basic background knowledge accessible. The target group for using the multimedia IBIS material in the first stage comprises about 2200 students per annum.

The following topics are to be dealt with in depth in EduBITE:

- The case study manufacturing enterprise DeBITE
- Business Engineering and Enterprise Modeling
- Architecture of Business Information Systems
- The architecture of ERP Systems, including related topics such as customizing and integration
- Sales and Distribution
- Materials Management
- Production Planning
- Financial Management and Controlling

Usability is guaranteed using specific style guides focused on by the EduBITE partner from Vorarlberg. Students will learn in the use case context of DeBITE, which enables a situate learning approach.

Students' learning objectives as well as their prior knowledge differ from course to course. Accordingly, learning processes and the required learning materials vary (e.g. for computer science students, business administration students, high school students, etc.). EduBITE develops a tool that enables to define metadata for learning objects, to declare learning processes and to configure individual multimedia course materials based on the learning object repository according to learning processes. This EduBITE-*Configurator* also allows the export of course materials according to a learning standard (see also (LOM), (SCORM), (IMS)), guaranteeing interoperability with various learning management systems.

The EduBITE Configurator will be realized by the EduBITE project partner from the University of Vienna which has just completed substantial preparatory work in this tool area. The Configurator will contain a modeling component in order to graphically describe the learning processes. The allocation of smallest learning units to the according part of the training process will be supported. With it's functionalities training processes can be easily modeled and training material can be professionally managed, but the main focus of the Configurator is the individual course production based on the idea of Learning on Demand. A specially designed interactive questionnaire will capture the actual knowledge demand of the focused target group. Based on this information the Configurator will automatically, based on reference processes, compose the required course. The course description will be in a standardized metadata format in order to assure compatibility to learning management systems through export/import interfaces.
One of the main questions coming up in this context is the warrantee of pedagogically right provision of course materials. To deliver a solution to the question of automatically building of courses from "instant" learning units and still having didactically right learning processes will be one of the biggest challenges of this project beside the technical realization of the Configurator.

During the end phase of the project the developed multimedia materials will be evaluated twice in typical project partner IBIS courses. WebCT will be used as the learning management system for these evaluations. Blended learning will be realized. Interaction and communication elements as well as group work will encourage learning during online phases.

After the evaluation, a rollout of project results to interested AKIT members is planned using the association as a multiplicator for the project results.

Project Architecture

The project architecture can be sketched as follows in figure 1. It also allows a continuous extension and update of the business process models of DeBITE by incorporating case studies from other enterprises as well as by adding further basic knowledge. Through meta description of the learning units the Configurator can always pick up and bond the demanded contents to a multimedia course. The use of other learning management systems besides WebCT is also possible as far as learning object standards are supported.

Basic Knowledge IBIS

Figure 1: EduBITE Architecture

Resume

The production of didactically well designed modular learning materials is an important precondition for a successful application in virtual learning. But this mostly goes beyond the capacity of individual teachers, and thorough learning object engineering is not enough to assure project success. EduBITE adds to the engineering process also a circumstanced approach using the extensive case study example DeBITE. It enables individual course configuration and also places the produced multimedia learning material in a co-operative environment. The AKIT association thus guarantees that the multimedia material outlives the duration of the project as well as it encourages future expansion and extension.

A user-oriented information system for Teleservice in trouble shooting of mobile construction machines

Achim Streit, Klaus Henning, Arne Simon

Centre for Learning and Knowledge Management and Department of Computer Science in Mechanical Engineering (ZLW/IMA), University of Technology (RWTH Aachen), Germany,
streit@zlw-ima.rwth-aachen.de, henning@zlw-ima.rwth-aachen.de, simon@zlw-ima.rwth-aachen.de

Abstract: The Teleservice information system describes a realisable alternative which is especially focused on the support of service technicians during the process of trouble shooting. The system transmits the relevant data to a browser whose lay-out design supports efficiently the mutual flow of information between the service close of the customer and close of the manufacturer. The thin-client-three-tier-architecture, the JAVA implementation of the System-Clients and the Application-Server and the physical data independence of the relational DBMS enable the adaptation of the information system to the needs of the user and the companies involved in the service process.

Keywords: Teleservice, information system, Java, relational DBMS, Design

1. Introduction

Due to the increasing pressure in competition the manufacturers of construction machines face the requirement to distinguish from the competitors by innovative product-related services. Technical communication across borders of nations and continents has become part of everyday life in industry and service. About all enterprises are stretching out their business into global activities. These would be "global players" need to develop and implement their own networks for their own staff as well as for their business partners world-wide, with different degrees of data access and communication requirements. Hence different layers of Intranet structures are to be implemented, integrating the different user groups in different ways, corresponding to their tasks within business co-operation.

2. Characteristics for Teleservice in civil engineering

Mobile construction machines in civil engineering (e. g. cranes, diggers, open cast mining machines or concrete and tarmac casting equipment) perform the most important functions on construction sites. In order to improve performance world-wide for the manufacturers the servicing of their mobile construction machines has to be efficient, reliable and first of all low in cost. Critical factors are the availability of spare parts and the quality and speed of diagnosis in case of machine failure.

The main problem in repair and maintenance, however, is decentralised technical information, involving different departments and people in the service process, different technical standards of the machines and insufficient maintenance infrastructure world-wide. Therefore an information system is needed which enables the variety of machine users and servicing staff to find the necessary information through one system. In order to develop a prototype for an user-oriented Teleservice information system (TeSIS) the required information for this service was structured and the involved persons and companies were identified and the work flow of an exemplary service process was described.

If a failure at a construction machine is determined by the machine operator or during an inspection, then usually the workers on customer side try to find the error. If the customer on the construction side is unable to repair the damage locally, he informs a service organisation oriented closer to the manufacturer. The reasons for this are often the lacking experience of the local technicians with the existing technology or missing information, e.g. the faulted construction unit is not sufficiently described in the service documentation (Henning et al., 2000).

The responsible service organisation decides, whether the manufacturer service must be contacted or to what extent they are able to solve the problem themselves. If the producers service is informed, the service has now the task to identify the problem. Usually there is no prescribed or firm operational sequence for a failure report. The service technician of the construction machine manufacturer tries to locate the error and arrange the necessary steps by remote diagnostics via telephone and fax.

Central term of the design field humans-technology is the man-machine interface. It contains all elements of the (information-) technical system, with which the user in its work activity acts or interacts. The overall system humans, organisation and technology describes the context of utilisation of a software for a special application area, the technical customer service at construction machines. The context of utilisation itself covers the handling of the humans with the technology, the integration of humans and technology in the organisation and the resulting task structure. The emphasis of this paper lies in the design of an information system for the customer service of a construction machine manufacturer.

3. Requirements

The requirements of a TeSIS, resulting from the process of the trouble shooting at mobile construction machines and the organisations which take part in it, can be illustrated in the application area. Fig. 1 summarises the requirements to the TeSIS. Under the term of task accomplishment requirements, which devoted from the task ($T_{T1..n}$) and requirements of the users ($T_{U1..n}$) itself are quoted. Requirements of the functionality of the information system result on the one hand from the task ($F_{T1..n}$) and on the other hand in connection with the application system ($F_{S1..n}$), which can be used. Usability means both requirements to the design of the application system ($U_{S1..n}$) and the needs of the users ($U_{U1..n}$).

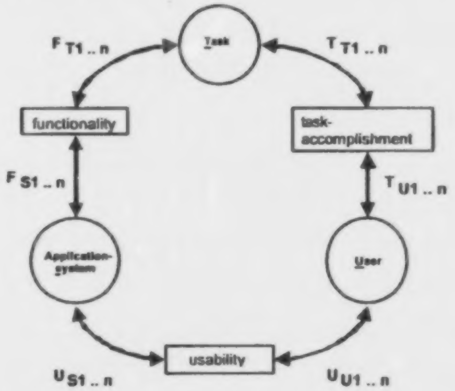

Figure 1: Requirements to a information system

4. Realisation

The presence of a person with service specialised knowledge at the machine is thus presupposed. The Teleservice information system realises an early manufacturer support for service-relevant problems. An overview of the Web-based TeSIS shows fig. 2. The TeSIS integrates two well-known Client server systems: InterNet and/or Www Client/Server, Java Client/Server and data base Client with the appending DBMS (Dickens, 1997). The user calls the needed application in form of an applet. Since the applet is merged in a HTML document, the Java-Client is also the Www-Client at the same time and in summary called System-Client. The Java-Server merges with the Database-Client into the Application-Server. Since the Application-Server is implemented not as an applet, but as a Java-Application, the middleware possesses the rights of a application and can arbitrary access resources of the data base management system (DBMS). The Application-Server controls the data base connection or the selection and a preparing of data from the DBMS. Both the System-Client and the Application-server of the TeSIS are realised in Java technology (Streit, 2002).

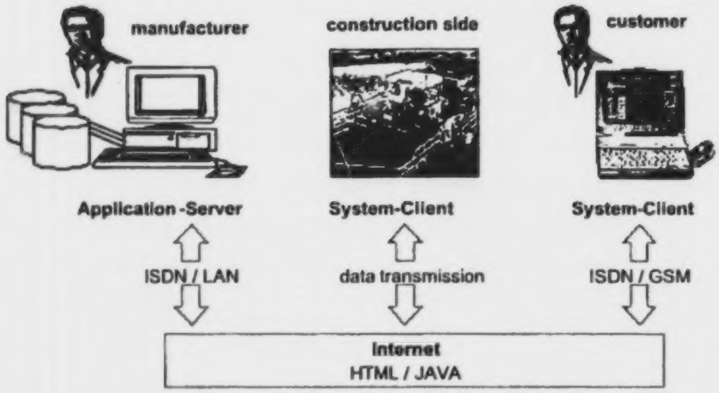

Figure 2: Teleservice information system

The consideration of the application range set the basis for the requirements to a TeSIS concerning the support of performance, the functionality and the usability. The whole design process has been performed in very close co-operation and involvement of the future users. The themes and issues to be called up by the system have been structured based on a cluster analysis made by the maintenance staff and technicians of the machines manufacturers. This early integration of the future users leads to a double advantage: Firstly, the acceptance of the software system by the future users is increased, because they see their wishes and thoughts about the design and structure of the user interface are integrated into the final layout. Secondly, the user integration has helped to prevent failures in the development of the application in the first phases of the project. It has lowered the costs and minimised the development time. By the integration of the users in all phases of the design process the TeSIS is adapted to the needs of the different user groups.

The user interface has to assist users with different native languages because the machines are in use around the world. Secondly the controls of the application have to be readable even under bad sight conditions e.g. on a laptop at the construction site. Thirdly there is no standardised strategy of trouble-shooting, every technician follows his individual strategy. Most of the technicians have worked for a long time in their jobs. These different individual problem solving strategies have to be supported by the application but it implies also that the users have to change elements of their own strategies.

Finally the acceptance of the user interface by the technicians is a specific problem in Teleservice: the computer knowledge of the world-wide users varies very strongly. Many of them have little or no experience with computers which makes it necessary to develop an easy-to-understand interface without limiting the efficiency of working with the system for the experienced user. In order to solve these problems, two different approaches have been used to develop the new interfaces.

Firstly a set of new simple icons has been designed which are fully self-explanatory for the technicians in civil engineering (see fig. 3, set of icons). Six main clusters of data have been identified to be the content of the database (Raue et al., 1999). They have been chosen according to their similarity of their sets of characteristics:

- online data of the machine (e. g. hydraulic pressure)
- producer information about the machines (e. g. product family catalogues, internal design drawings)
- forms (e. g. failure reports, order lists)
- maintenance and repair information for diagnosis (e. g. checklists, failure identification)
- job lists
- additional information (e. g. route maps, hotel lists, web-sites)

These clusters have been derived in very close communication and exchange of observations with the maintenance staff and the machine users. Subsequently they helped to structure the new www-based information system to support the service of these machines.

Secondly, the hierarchical structure of the application has been kept extremely simple and transparent. On each level, only a very small number of options is being offered to the user in order to make the path to the wanted information a sequence of easy-to-remember decisions based on the new simple icons (see fig. 3).

BEST COPY AVAILABLE

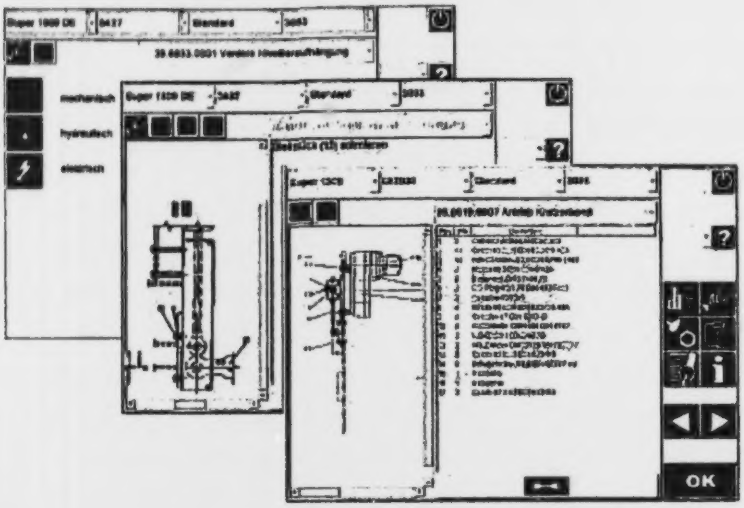

Figure 3: Computer Interfaces for the Teleservice of Civil Engineering Machines

For the unique identifier of the machine e.g. only the input of the type of machine, the machine number, the type of plank and the plank number is necessary. The surface offers now different ways of diagnosis to the service technician. With respect to the diagnostic support, an error search tree and a symptom list rank, mechanical, hydraulic and electrical causes are included. In the second level the parts lists is displayed in combination with the spare part drawing. On the third and fourth level methodologies for remedy are suggested by symptoms and cause.

5. Conclusion

The prototype of a TeSIS provides a basis for a successful integration of new services in the traditional product portfolio of manufacturers of construction machines. The system developed can be considered an example of how Intranet structures can be implemented within the existing Internet. Through easy access regulations and organisational agreements a large group of machine users world-wide can become integrated into enterprise Intranet in order to make best use of the available knowledge of the enterprise. Since the TeSIS can be integrated in the existing intranet, it offers furthermore the possibility to the manufacturers to make information of the service department internally also available to departments like development, production or training. This increases the utility of the product for the customer and enables the company to gather advantage in knowledge over the competitors.

E-mail: suga@limu.is.kyushu-u.ac.jp

Abstract: When lecture scenes are videoed for the distant lecture, a camera-person usually controls a camera to take suitable shots; alternatively, the camera is static and captures the same location all the time. Both of them, however, have some defects. It is necessary to control a camera automatically. We are developing ACE (Automatic Camera control system for Education) with computer vision techniques. The early version of ACE captures the lecture focusing on the latest object written on the blackboard. When noting something written on it or thinking over them, however, students may not always want to watch the latest object. We designed a recording function of the scene captured by ACE before for one of the solutions of this problem.

1 Introduction

The growth of a communication network technology enables people to take part in distant lectures. There are mainly two kinds of method to held a distant lecture. One is an web-page-based method and the other is a method of sending visual and audio of lecture scenes. We are studying a camera control system for the distant lecture held by the method of sending visual of lecture scenes[Suganuma 1997a, Suganuma 1997b]. We call it "ACE" (Automatic Camera control system for Education)[Suganuma 2002].

A traditional style lecture held in a normal classroom is the target videoed by ACE. Figure 1 illustrates the distant lecture we envisage. A teacher teaches his students in an ordinary classroom. There is a blackboard in the room. A teacher writes and explains something on it. Some video cameras are setting in the room in order to capture a lecture scene. The scene is sent to a distant room and projected on a screen. Students in the room take part in the lecture by watching the scene on the screen.

Nowadays, some teachers use an OHP and/or other visual facilities in his lecture. Indeed many lectures such as in the information technology or the programming are frequently held by using visual facilities or computers in many universities b But there are still many traditional style lectures, in which a teacher explains something with a blackboard. It seems that such lectures will not disappear in the future although they will hold by combining the blackboard and a visual facility such as an OHP or Power Point software. We are, consequently, developing ACE for the distant lecture with videoing the traditional lecture.

When a lecture screen is videoed, a camera-person usually controls a camera to take suitable shots; alternatively, the camera is static and captures the same location all the time. However, it is not easy to employ a camera-person for every occasion. And the scene videoed by a steady camera hardly gives us a feeling of the live lecture. It is necessary to control a camera automatically. ACE enables people to do it for taking suitable shots for a distant lecture. Receiving a scene from a camera, ACE analyses it and recognizes the complexion on the lecture. ACE judges an important thing in the scene and effectively controls the camera to focus on it.

The early version of ACE captured a lecture scene focusing on the latest object written on the blackboard. When noting something written on it or thinking over them, however, students may not always want to watch the latest object. We designed a function recording the scene captured by ACE before as one of the solutions of this problem.

In this paper, section 2 presents design of ACE and our strategy of a camera control and a recording function. Section 3 describes an implementation of the recording function and section 4 describes an evaluation of ACE. Finally, concluding remarks are given in section 5.

Figure 2: An Overview of ACE

2 Overview of ACE

2.1 Design

When we designed ACE, which is an application based on Computer Vision Technique, we assumed the following:

- A teacher teaches his students by using only a blackboard.
- Students aren't reflected in the scenes captured by the camera.
- A teacher doesn't give ACE a special cue.
- Each student in the distant room are assigned a PC to refer what he wants.

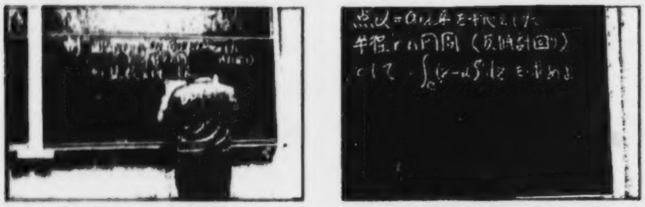
The first three assumptions are made when we designed the early version of ACE. The first assumption means the lecture captured by ACE is a traditional one, the second is assumed to decrease processing costs, and the third denotes a teacher is able to concentrate his attention on his teaching. These are realistic assumptions and the early version of ACE have been developed on them. The last assumption may not satisfy in same classroom. But ACE needs an interface to detect a student's demand and to display the requested scene. We adopted an Web browser as the interface. We make the browser run on the PC assigned to each student and supply the scenes as Web pages consisting of a still image.

An overview of ACE is shown in Figure 2. ACE requires two cameras. One is a steady camera and the other is a active one. The steady one captures a whole blackboard at a constant angle. The captured image is sent to an image processing component of ACE running on PC1 over an IEEE-1394 protocol. The component analyzes the sent image and decide how to control the active camera according to a camera control strategy shown in section 2.2. The control signals are sent to the active camera over an RS-232C protocol. The active camera, hereby, takes a suitable shot. ACE has a recording component which generates effective still image files from the scene captured by the active camera. It runs on PC2 because the procedure of the image processing component requires high CPU power. It receives a status of the active camera from the image processing component, analyzes the scene sent from the active camera and makes a decision whether to generate a still image file or not. A visual captured by the active camera and an audio picked up by a microphone are sent to the distant room. Students in the distant classroom watch and listen to them.

2.2 A camera control strategy

What does ACE capture? It is a very important thing for the system such as ACE. One solution is to take the scenes that students want to watch, but in this case many scenes are probably requested by many students at the same time. Although this solution needs the consensus of all students, it is very difficult to make it. We adopted, therefore, a strategy that ACE captures something explained by a teacher. However to extract directly what a teacher explains is very difficult. Consequently, we made an assumption that the latest object written on the blackboard closely

BEST COPY AVAILABLE



(a) An ordinary shot

(b) A key shot

Figure 3: Sample shots of a lecture scene captured by ACE

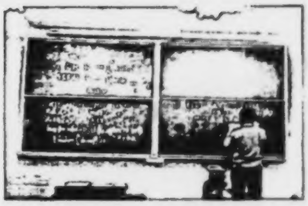


Figure 4: A sample shot captured by a steady camera

parallel something explained by a teacher because he frequently explains the latest object. ACE captures the latest object written on the blackboard.

It is important that students can easily read contents on the blackboard. A sample shot captured by ACE is shown in Figure 3. ACE usually takes a shot containing the latest object and a region near it in a discernible size. The blackboard often consists of four or six small boards like a picture of Figure 4 and a teacher frequently writes relational objects within one board. Now, ACE takes a shot by the small board such as Figure 3-(a). ACE takes a shot zoomed in on the latest object such as Figure 3-(b) after the teacher has written it. After a-few-second zooming, ACE takes an ordinary shot again. On the other hand, if we take a scene by a steady camera, the shot may be like a shot in Figure 4. In this case, the characters in this shot are too small for students to read because the camera must capture the whole blackboard. The shot of ACE is superior to that of the steady camera.

2.3 A recording strategy

Indeed ACE captures the objects explained by a teacher, but some students probably want to watch another object. ACE has a recording function of the scene captured by the active camera before. Objects on the blackboard doesn't change when once a teacher writes or erases them. If a object is updated, it is detect as the latest object again. This is reason why a still image is good enough for sending information. We decided that the ordinary shot, which consists of a small board containing the latest object in a discernible size, was recorded because a teacher often wrote a meaningful object on one small board.

A sample of a interface to students is shown in Figure 5. This Web page has two frames. In the left one, some still images of a small board are placed in order of generating, and in the right one, the images are placed in its position. When clicking each image, students can watch its enlarged image.

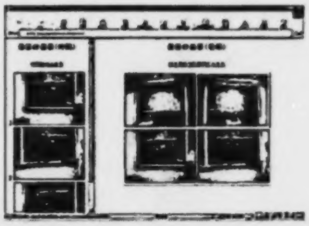

Figure 5: A sample of displaying small boards on which a teacher wrote some objects

3 Implementation of ACE

ACE has two components: an image processing component and a recording component. The image processing component extracts the latest object on a blackboard with some CV techniques and detects the timing of zooming in. For detailed implementation of the image processing, please see [Suganuma 2002].

The recording component of ACE gets the status of the active camera from the image processing component. ACE can easily generate an image from the ordinary shot according to the status. The ordinary shot, however, is not always suitable for the stored image. ACE have to estimate whether the objects on the small board is the same as that in the image which has been stored already. The image does not have to be stored if it has been already stored. The component checks it whenever the status of the active camera changes from a key shot into an ordinary shot.

Contents on the blackboard in the stored image have to be clear. A teacher sometimes occludes the contents in the ordinary shots. Then, the recording component also has to check whether he does not occlude the contents on

BEST COPY AVAILABLE

the blackboard. The image processing component detects a teacher's region with the subsection image between two successive frames. The technique, however, sometimes extracts only a part of teacher's body or sometimes misses a teacher. So the position of the teacher sent from the image processing component is not good enough.

The recording component detects a teacher in the image captured by the active camera. The ordinary shot contains the whole small board, so four edges of the board appears a complete rectangle in the image. If the teacher is in front of the board, the bottom edge is divided into two pieces. When the edge is completely connected, the component guesses that a teacher does not occlude the board, and stores the shot from the active camera.

4 Evaluation

We evaluated the videoing strategy of ACE with a real lecture from a point of view that students could made a note. In our experiment, we didn't use our recording function because we couldn't use a classroom where there are PCs assigned to our students. Before the lecture, we informed the students that we would collect their notes after the lecture and check them. We precomposed a master note and wrote the all contents of it on the blackboard. After the lecture, we collected their notes, compared them with the master note, and counted their missing in each note. 36% of all the students can perfectly copy the contents from the shots captured by ACE and 45% of the students make only one mistake. Almost all students make not more than three mistakes. Some small characters such as the index of formulas caused almost all mistakes. As the results of this estimation, almost all students can make a note correctly enough to learn it. The shots of ACE seem good enough.

We also evaluated ACE separately in terms of the size of character in the still image, the timing of storing the image and the occlusion. The characters in almost all (98%) images are large enough for students to read. Those of 1.5% images are too small because they contain very small alphabets such as the index of formulas, which are originally written small by the teacher. Indeed mis-storing sometimes occurs because the image processing component miss the latest object, but almost all still images are worth recording.

5 Conclusion

ACE takes a suitable shot if the teacher explains the object as soon as he writes on the board. It cannot take, however, a suitable shot when he explains something in front of it and when he explains something written before. In the former case, he has to change his position because his students even in the local classroom can not watch them. In the latter case, the teacher usually teaches his students pointing the object which he wants them to look at. We will get ACE to interpret teacher's action and/or posture and to capture more suitable scene. We assumed that a teacher teaches his students with only a blackboard. But he sometimes also uses with a visual facility. We will also get ACE to apply to such a situation.

Linux and the Rise of Open Source Software: the Indian Perspective

Yogesh Suman, Scientist, NISTADS, K.S.Krishnan Marg, Pusa, New Delhi-12, India.
Email geetyogesh@yahoo.com

Abstract: The paper describes the concept of open source software with reference to Linux. It describes the consequences of closed source software strategy followed by commercial companies. Discusses the strengths of Linux operating system. Gives the roadblocks in popularization of Linux. It also gives the global market standings of Linux. Gives Indian perspective of the Linux, how it can be helpful in solving the problems faced by poor countries like India in implementation of information technology for development

Introduction

Information Technology is currently a major concern of developing countries. It is a technology vital for development but the cost is high and implementation not easily achieved. A related issue is that of copyright and illegal copying of software. Complying with international standards means ending widespread copying of software endemic in most developing countries and the prospect of very high and recurrent software costs. Other problematic issues are security and virus problems. A recent development, which is attracting much interest, especially in developing countries, is that of open source software and the Linux operating system in particular. This type of software goes a long way in helping to resolve the issues mentioned above. The most basic definition of open source software (OSS) is software for which the source code is distributed along with the executable program, and which includes a license allowing anyone to modify and redistribute the software. Source code is the human readable set of instructions which programmers write to create a piece of software. But once a program has been "compiled" into a machine-readable form its source code is irretrievable. It is practically impossible to make changes to a program without having a copy of its source code. If a program's license includes the right to modify the program, this right is meaningless unless the source code is readily available. It is at this point open source software differs from other software which is not open source. Almost all the commercial software companies distribute their software products in machine-readable form only. By doing so they maintain a monopoly on improving their software by adding features or fixing bugs. This power encourages them to behave the way monopolists often do: bugs do not get fixed unless this brings a profit, and upgrades become expensive because there are no competitors.This is how, many experts believe that large commercial software companies have gained monopolistic market share of the strategic system and application software for personal computers. According to them the strategy of these companies include predatory pricing (cutting prices to drive rivals out of business); cross-subsidies (using one part of a large company to underwrite loss-making activities in another); and technological predation (using inside knowledge of the operating system to make rival's programs run badly). Browsers' war (the war between Microsoft's Internet explorer (IE) and Netscape navigator) can be a good example. In this Microsoft was at advantage in the sense that it controlled the source code of Windows operating system. Since both IE and Netscape Navigator were to run under Windows. It was easier for Microsoft to develop Window based Internet browser than any other company.These strategies adopted by commercial software companies, has given rise to unhealthy dependence on proprietary software, huge expenditure on licensing fee, growth of gray market in pirated software, troublesome environment in local software industries and most importantly discouraged innovation in the software industry at global level. The freedom of innovation offered by Linux has to be understood against this background.Although the concept of open source software started to attract people's attention in eighties, it gained real momentum in 1990s with the rise of Linux, which is emerging as powerful OS for enterprises as well as private use.

Strengths of Linux

The inputs from tens of thousands of independent developers ensure that highly creative, innovative development is constantly happening. The race to outdo each other ultimately benefits Linux and customer. Apart from being free Linux has following technical features:

- **Robust**: Need to reboot the system after making Operating System (OS) level changes is reduced.
- **Secure**: The very fact that every line of code is analyzed by thousands of people of open source community, means that no hacker has a chance to slip in anything unnoticed. It is widely seen that Linux has had no high-level security defect remain open for more than 48 hours. That's an achievement that no single company hopes to emulate easily.
- **Scalable**: Linux runs on almost all hardware platforms, from a wristwatch to a mainframe. Such scalability is not even available to an OS running on limited platforms.
- **Manageable**: Linux is essentially self-maintaining. Turn it on, configure it and forget about it.
- **Cost-effective**: Linux is free to use, free to copy and free to redistribute. No licensing required.
- **Can replace windows:** For every proprietary, licensed software there exists a practicable free Linux alternative.
- **Multitasking capability:** Linux is one of the few operating systems apart from Win NT, which does preemptive multitasking. Win 3.1, Win 95 and Mac OS all do cooperative Multitasking.
- **Integration with existing LAN**: It has support for all the popular protocols so setting it up to access the Internet is a really simple and quick task.
- **Gaining popularity as the number one server solution:** The global economic recession may actually provide competitive advantage to Linux. A recession will simply drive enterprises as well as private users to seek more cost-effective solutions. Indian customers are interested in Linux because of the price/performance advantage of open-source software running on commodity servers.
- **Range of users:** Linux has gained so much popularity in the past two years that there are actually few corporations left that are not using it.
- **Services offered:** Linux offers such a vide range of services that almost every single Linux server installed on low-end PCs lands up being the most mission-critical system in the entire organization.

Indian perspective

India is talent-rich, resource-poor powerhouse of immense software skills. But it also finds itself ironically unable to afford the prices of 'legal' software that it very badly needs for itself. If legal software becomes mandatory, most people would cease to use computers and usage would go down harming us more. On the other hand, if India continues to pirate software, the country gets a bad name in the intellectual property corridors worldwide. So given that piracy is no long-term solution this availability of Linux for no cost is specially important for Indians who are squeezed between astronomical software prices, the falling value of the rupee, and allegations that those who cannot afford to pay are 'pirates'. For India Linux represents generous scientific altruism over exclusive, profit-driven business compulsions. So far the growth of Indian IT has remained US centric and the domestic sector has been completely neglected this has resulted in extremely weak domestic sector. The current IT slowdown in the country is a direct result of the slowdown in US economy. On the other hand countries like China has been able to sustain the growth despite the global slowdown only because of the strong domestic sector. Now the question comes how to make domestic sector strong in India. In order to make Indian IT strong at domestic front the mass penetration of PC has to be increased. The main hurdles, which India is faced with, are the following:

- Most people can't afford to buy a PC.
- Most people can't afford to buy legal software.
- Almost 90% of people in the country can't understand English, which is the main language, used in software products.

Linux can go a long way in solving the problems mentioned above.

Cost Effective PCs: Linux can help in developing cost effective PCs in India because of the support it has for obsolete hardware and it's ability to be used as embedded OS in small hardware applications. Indian Institute of Sciences Bangalore has developed simputer, a small hand held device that runs on Linux operating system and can be used for checking and sending emails without being confined to a single point. More importantly it can operate in local language as well.

Language hurdle: Linux is available with the source code, which means the basic Kernel making the software can be easily customized to local languages and local language version of Linux can be easily developed. Indian Institute of Technology (Chennai, India) has already started developing the local language version of Linux so that people who don't understand English can also operate computers. This kind of solution can go a long way in realizing the dream of IT for all.

Impact on education: Free software available with source code allows teachers and students to look into the software and not just treat it as a mystical black box. Just as children like to play with things, tear them apart and put things back. Free software encourages such exploration, allows interaction with other users & developers, and learns to understand large complex programs.

Linux in indigenous supercomputer: C-DAC (Center for Development of Advanced Computing, Pune, India) has proposed to develop a Supercomputer based on cluster computing with PCs using Linux as a starting point. The combination of Linux and the PC will enable these clusters to be available readily and cheaply.

Linux Roadblocks

Support availability and cost: This has been the weakest part of Linux ever since the beginning. Many potential Linux users are waiting for a reliable support infrastructure to arrive. That's why 24/7 service providers are wary of switching to Linux. Windows NT or Unix users are assured of support at a call. This is a remote possibility in Linux today. One can't expect people to log onto the Net, shoot off a query and wait for a reply. Most businesses don't want to pay for support, least of all when the support is for a free solution. Yet this is precisely the revenue model that Linux distributors have adopted. And mainstream corporate IT users tend to be more comfortable with fixed costs than with variable costs. Though the support is available, it remains to be seen how the users take to its costs.

Away from desktop: Linux is still at some distance from desktop systems. Until the operating system manages to come up with a body of applications to compare with the tens of thousands available for Windows, it will not be able to match it. Windows has the advantage of being preinstalled on most personal computers being shipped by big firms, and that is not likely to change in the near future.

Global Standings:

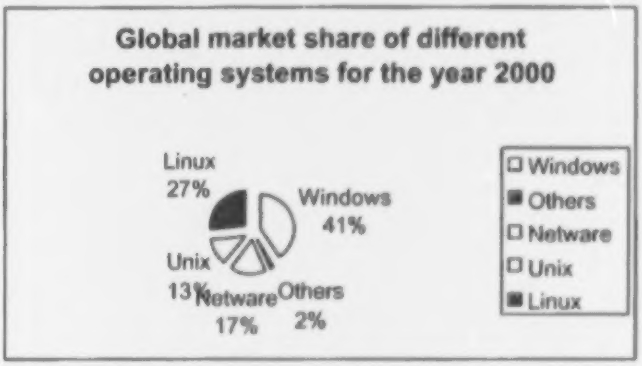

Table 1: Based on research done by IDC (International data corporation)

Linux grew by 24 % as against 20 % growth registered by Microsoft Windows in the year 2000. Current Linux usage in Indian corporate stands at 5 %, which is likely to reach 9% in 2002.

Conclusion

Free operating systems like Linux represents great opportunity for poor countries like India both in terms of low cost and availability of source code. It can really increase the affordability of computers. Easy customization of Linux can help in destroying language barriers in understanding the software products. By doing so it can really increase the mass penetration of IT in countries like India thereby making the benefits if IT available for all.

Abstract
Most organizations have high hopes regarding the potential for eLearning to address the increasing demands for constant learning that characterizes life in a knowledge society. However, most existing designs are strongly influenced by traditional classroom-based education, and are consequently poorly adapted to the situated conditions of real work practices. This paper aim at framing a research domain labeled *work-integrated learning*, where focus is set on developing innovative tools and methods for technology-mediated learning rooted in understanding of the specific conditions for various organizational settings. The paper proposes a four-level stage model as a framework for both analysis of organizations and design of new tools and methods for eLearning.

1. Introduction

Today's organizations are experiencing an increasing challenge of adapting to the potential of new generations of information and communication technologies (ICT) (Bra et al. 2000; Dahlbom & Ljungberg 1998). This challenge encompasses a complex web of interrelated problems such as competencies in buying, implementing, and maintaining ICT systems aiming at supporting collaboration, communication, work and learning processes. This background reveals a paradoxical conflict between the extending faith in the potential of ICT as a mean for effective change of the organization, and the problems that arise when this potential is going to be realized in the organization. There is a lack of knowledge about what factors and mechanisms actually cause this paradox between vision and practice in the adaptation of ICT. A second paradox lies in the fact that technological innovations significantly contribute to a growing need for employees to continuously learn of new tools, skills and acquire competencies (Magnusson et al. 2000), while at the same time there is a tendency to turn to these technologies when looking for new ways to address the problem of increased need for learning (Svensson 2002). Computer mediated education in various forms, often referred to as elearning, has rapidly manifested itself as an area of great interest within this context. However, traditional educational concepts are poorly adapted to these problems. There is a need for innovative methods and models that are anchored in the real work settings that organizations are experiencing. Learning in an organizational setting must not only be understood in terms of organized forms of training and education, but also as informal processes of sharing, creating and disseminating knowledge throughout the organization (Brown & Duguid, 1991; Sørensen & Snis, 2001).

2. Work-Integrated Learning

The term work integrated learning is proposed as a concept stressing that learning is situated in the work practice of the learner. Learning should accordingly not be perceived as an activity separated from other work activities, but rather as a constantly present part of all work (Lave & Wenger 1991; Brown & Duguid

1991). Organized education and informal knowledge management processes are inseparable from and integrated with the everyday work practice that constitutes a context for the learner's reflections, self or together with others (Cook & Brown 1999). Studying work integrated learning from an Informatics-perspective means highlighting the use of technology. In the context of work and learning technology is far from uncomplicated. When interaction in a community is mediated by ICT, dissonance with respect to how the individual members perceives and makes sense of the technology can seriously obstruct communication and learning, (Orlikowski, 1992). Other aspects that could affect the conditions for learning are availability, access, and problems related to information and interaction overload (Ljungberg & Sørensen, 2000).

3. Research Agenda

The project introduces a research focus that involves social, cultural, technological and pedagogical dimensions. The overall research objective is to explore and understand these dimensions and how they interact, in order to arrive at a knowledge platform that could constitute the base for design of ICT systems that supports communities of work integrated learning. Adopting a holistic approach to work integrated learning that encompasses organized and formal, as well as spontaneous and informal activities, and treating knowledge and learning as processes of social construct rather than objects, implies a collaborative constructivist view on ICT and learning. (See for example, Fjuk 1998; Nuldén 1999). Furthermore, focusing on the situatedness and the social dimensions of learning suggest that Lave and Wenger (1991) and their theory of legitimate peripheral participation could constitute a fruitful analytical lens. Studying communities of work integrated learning should involve workplace case studies where the unit of analysis could be the individual learner as well as groups of collaborating learners (Luff et al. 2000). The empirical approach will be dominated by ethnographical methods such as participant observations, semi-structured interviews and document analysis (see for ex. McCracken 1988). The element of design that is incorporated in the research agenda suggests an action-oriented approach, such as the action-case (Braa & Vidgen 2000)

4. Research Context

This paper report from an ongoing longitudinal research project aimed at exploring the landscape of distributed electronic work-integrated learning (WIL). The project involves two parallel, yet interwoven, research approaches: (1) Extracting the conditions for WIL through exploration of typified organizational work settings, thereby acknowledging the situated nature of work and learning. (2) Designing innovative tools and methods for WIL through action-oriented trials and field experiments. The project is divided into two typified abstract cases each representing a cluster of questions and organizational characteristics. (1) The e-learn case is directed towards formal and organized forms of computer-mediated education conducted in both small and large organizations, and (2) the prof-net (professional networks) case focuses on informal and emergent online-learning communities.

5. Preliminary Results

During the first six months of 2002, two pilot studies have been launched within the eLearn frame. The first study focuses on small enterprises with 2-15 employees, all customers to the same Swedish bank. The research was triggered by the perceived difficulties of training computer illiterate customers in computer usage. Earlier efforts used traditional classroom-based concepts, with poor performance and high drop out rates as a result. Therefore the bank initiated an action-based project with the aim to explore new methods for developing the competence of its small business customers. The second study is conducted in collaboration with a large organization in the public sector. The aim is to create a "web-academy" where professionals in specialized areas from various regions of Sweden can use Internet technologies to facilitate training as well as creation and sharing of new domain knowledge. The preliminary findings underscore the importance of methods and application being adapted to the individual and situated conditions. The initial experiences from the exploratory ethnographical studies leads us to propose a maturity stage model for work-integrated learning (Fig. 1). The model could serve as both a framework for analysis of the maturity of an organization, and as a design space for educational concepts and ICT tools.

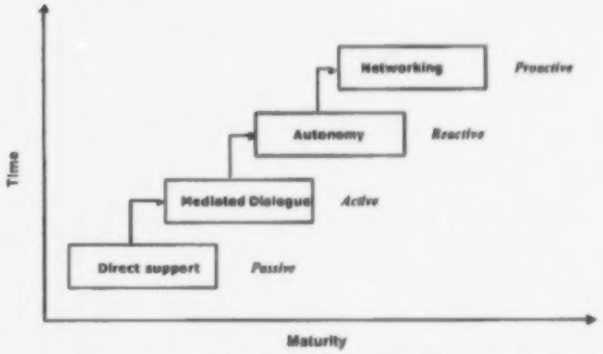

Figure 1: A maturity stage model for Work-Integrated Learning

The stage model suggests that each learner must mature through underlying levels before being receptive to educational concepts on a certain level. Even though the model is primarily constructed to inspire innovation of new designs, it is also possible to map traditional and widespread methods and tools into the framework. The two first stages are grounded in the empirical findings from the pilot studies, the subsequent stages will be tested and evaluated in further research. Each stage of the model is briefly outlined in the following subsections.

5.1. Support

This represents a stage where users are computer illiterate, and consequently cannot address technical problem or posses the language to communicate their shortcomings. They are typically extremely short of time (and motivation) for learning. The focus is strongly directed to urgent short time problems, which needs immediate attention. Learning is best facilitated through direct face-to-face or remote control-based support concerning real work-related problems.

5.2. Dialogue

When IT-skills increase learners were found to respond well to computer-mediated tutoring, using asynchronous and synchronous web-tools, such as threaded discussion forums (Svensson, 2002) and chat rooms. These learners were also found to be more active in trying to solve their problems. However, the focus is still primarily directed towards urgent needs.

5.3. Autonomy

This stage is suggested to describe a user who is mature enough to reactively use the Internet and other online resources for his/hers learning. The autonomy stage is also believed to be characterized by users with a more visionary long-term business focus. This stage comprises most traditional elearning concepts that are dominated by hypermedia user-content interaction (Moore, 1993).

5.4. Networking

Finally autonomous users can participate in existing, or form emergent, online-communities (Svensson, 2002) corresponding to their learning objectives. Learning within such communities is highly collaborative and knowledge is constructed through processes of mutual engagement (Wenger, 1998; Swan et al. 1999). Innovative knowledge creation on the level of the learning community makes this stage potentially proactive with regards to the business strategy of each participating individual.

6. Further Work

The next phase of the project aims at evaluating and developing the framework through a combination of exploratory analysis and design trials within the elearn and profnet case-programs. During the spring of 2003 a large study directed towards the emergent use-patterns of a new corporate Intranet designed for organizational learning and knowledge creation will be launched.

Facilitating on iTV: A Call for Broadcast Communication Style & Voice Management

Sharifah Nur Anthasha btc. Syed Ahmad
Centre for Innovative Education
Faculty of Creative Multimedia
Multimedia University
Malaysia
anthasha@mmu.edu.my

Abstract: This paper is a study of radio and television delivery-skills, the communication style and voice management of the electronic medium; and how they are adapted to the needs and requirements of iTV facilitators, forming a module or guide, if not a set of qualifying standards. Interviews with facilitators and broadcast presenters and trainers, surveys on educators and learners in traditional and virtual classrooms, and self-experiences in vocal management training and television presentation, mainly form the basis for recommendations and conclusions. Findings indicate that facilitators must be content-adept, technology-conscious, and practicing communication principles to be effective, good broadcast communication style and voice management, having had sound knowledge on voice quality, speech personality and physical delivery

Introduction

A lot has been reported on the convenience and technological successes of the virtual mode of delivering knowledge, but not much attention has been paid on the act of delivery itself. This is based on the assumption that "…iTV teaching does not require modifications in teaching style and that a teacher can continue to teach just as he or she has in the traditional classroom…" (Hobbs & Christianson, 1997, pp. 184). So, how do teachers deliver structured knowledge in an environment strikingly different from the traditional classroom? How is it comfortable or significant to talk to an "audience-less" classroom that is void of students' familiar non-verbal cues or body language confirming comprehension or indicating otherwise? How do you substitute your own body language to emphasise and support your communicated message of knowledge in the electronic environment? Fortunately "…iTV educators have recently realised that they may have been short-sighted in adopting the goal of duplicating the traditional classroom and are now using technology as an opportunity to modify their teaching techniques" (Hobbs & Christianson, 1997, pp. 184).

Delivery, obviously, is an important component of teaching and learning that needs undivided attention and consideration as we take education into the virtual realm. In this time and age, being content-confident alone is insufficient for the educator to be effective. This unprecedented role is indeed crucial to the success of virtual learning, besides justifying the sophistication of technology. Thus, it is important to have a talented and effective facilitator as he/she "... plays a key part of the virtual classroom model, controlling content, and facilitating interaction with and among students in a resource-rich environment. The absence of an instructor or facilitator is the key reason why the world's best multimedia courseware, Web site, or instructional CD-ROM will not, by itself, be as effective as a virtual classroom" (Bernstein, O'Keefe, Usluel, Wilson 1997).

The Study

With delivery in focus, this research looks into the facilitator's communication style and voice management in facilitating the virtual classroom. Broadcast presentation skills of both radio and television have been proposed given their nature of communication that is designed for the absent audience, with listenable properties intentionally built into it, through the electronic medium. We look at television especially for on-camera performance and, on how to gain tele-presence; we also look at both radio and television for communication style and voice management – speech characteristics, non-verbal communication, vocal projection and control suited to the target audience. These are essential, as many distance-learning technologies actually demands a presentation personality, which requires more energy, smoothness in delivery, and projection of gestures and voice than presentations made within a classroom. Because distance-learning sessions may be taped, the quality of the presentation should be uniformly high for every session (Porter, 1997, pp.201).

The adoption of television delivery-skills for iTV facilitating could appear to be an obvious choice. Nevertheless, not much thought has been put into it, given lack of, if not at all, source of references or guides in preparing educators for the screen. iTV in any format is primarily a visual medium where verbal and non-verbal presentations are most important.

Interviews conducted with radio and television presenters cover issues, among others, of how communication or speaking style on radio and television is similar to or different from that of face-to-face communication, what is it like speaking to a camera, what are the techniques adopted to appear natural in front of the camera, how important is non-verbal communication in radio and television presentation, to what extent does it enhance verbal communication, how does good voice management affect presentation. Also questioned were workshop facilitators and motivators on, among others, what the role of a facilitator defines, what it takes to be a good facilitator, how to hold learner's interest and keep the motivation level up all the time, how much importance is given to voice production and expression, non-verbal communication, and how to gauge learner's understanding especially when he/she is physically remote.

Traditional and virtual classroom observations are conducted to identify and understand teacher and facilitator's, as well as learner's limitations in the process of knowledge transfer. Aspects taken into consideration are teacher and facilitator's level of confidence in the subject matter, competence in the English language (standard delivery language), adjustment to the physical/virtual setting, and medium preference. Learners are asked on their understanding of the subject matter, their level of satisfaction on the way it is delivered, the lecturer and facilitator's verbal and non-verbal communication, and medium preference.

Findings

Knowing how to communicate effectively with non-verbal expressions may be more important than what is said. What more when communication has been suggested to be 75% non-verbal and iTV in any format is a visual medium that exaggerates all of an educator's best features. Knowing what makes him/her special in terms of how he/she looks, sounds, and moves will enhance an educator's teaching abilities (www.zianet.com). In this regards, this research also serves to provide an opportunity to identify the educator's special features. Thus, it is obvious that the major challenge in video-based tele-learning for the instructor involved is also how to perform on camera. The instructor must learn how to be more than a talking head, which is both a matter of television-handling skill and pedagogical insight (Collis, 1996).

Meanwhile, Frenkel (1995 in Collis, 1996) places the emphasis on educator's tele-presence, "...while the core of the correspondence-stream of distance education is the assumption that the lesson-presentation skills of the teacher can be represented through well-designed print materials, the core of the "video" stream of distance education is to use technologies and pedagogical techniques to make it seem as much as possible that the distant student is sitting in the face-to-face classroom of the teacher. This can be called *tele-presence: Being there while being here* or *being there without having to.* Thus 'teaching' in the familiar ways of lesson presentation by the instructor, questioning, and feedback-giving exchanges with students during the lesson, is to be maintained. Interactive television and two-way video make this most directly possible, providing some immediate opportunity for the questioning and student-instructor interaction to occur."

It must not be overlooked that educators in reality, though appearing virtually to learners, are motivators as well. Keller (1983) in Hobbs & Christianson, 1997, pp. 186, stated 4 elements of learner motivation directly applicable to the iTV-learning environment. An iTV facilitator should be able to hold learner's ***interest*** – having the ability to engage and sustain learner curiosity and attention directly impacts the degree to which commitment to learning will occur; see and state the ***relevance*** i.e. able to relate learned information and concepts to individual needs or goals is important. Instructional content should be related to the world of work, higher education expectations, or to practical skills; instil ***confidence*** among learners where they must perceive some likelihood that they will be successful; and, provide learner with ***satisfaction*** - reinforcement of the learning process is vital. By combining extrinsic rewards and intrinsic motivation, students will be more likely to pursue or continue to pursue learning goals. Speculand sums it by saying that the facilitator's role is twofold – to deliver the message and, to be conscious of how it is delivered.

In voice management, educators must develop good attitude and think positively as the voice creates character, mood, situation, and feeling within the scope of the learner's imagination. This involves proper breathing, volume, gesturing, and posture, all towards producing broadcast quality voice.

Conclusion

Because traditional classroom teaching has the advantage of having teacher's immediacy and immediate learner's feedback, it is important for virtual facilitating to be personal, enthusiastic and warm yet authoritative, and engaging non-verbally.

Complementing this is proper voice management, with pre-requisites in the knowledge of voice quality, speech personality and physical delivery. As a facilitator, one must be content-adept, technology-conscious and practicing communication principles.

The Use of Style Guides in the Development of Online Documentation and Computer-Based Training: A Survey

Michael Szabo, Ph.D. and David Lemiski, M.Ed.
University of Alberta
Edmonton, AB Canada
mike.Szabo@ualberta.ca

Abstract: This study examines the purpose and use of style guides in the development of corporate online documentation and computer-based training (CBT) systems. The study was also used to determine if organizations currently developing online documentation and CBT projects research, develop, and use style guides specific to the needs of their organization, and what implications the use of a style guide has had on their projects. Ten developers of online documentation and CBT projects participated in this study. Comparisons of the results of their input on a standard questionnaire showed that the development and use of a style guide assists in the overall development of an online documentation project or CBT system, and that the failure to use a formalized style guide resulted in additional time spent in redefining screen elements.

Overview

This study sought to assess the impact of style guides for computer-based materials which are delivered online. Issues and the problem statement are presented first. A review of literature is followed by the research study and results.

Issues to be Considered

Organizations have developed and adopted style guides for print documentation to ensure that all documentation produced is consistent in format and presentation. The lack of use of a style guide in the development of CBT projects has been proven to generate inconsistency in printed documents, result in a requirement for more development time (Allen 1995), and be detrimental to customer satisfaction.

Problem Statement

It was hypothesized that few corporations currently developing computer-based materials have developed internal style guides for online delivery of materials. For those organizations without a style guide for online delivery, it is hypothesized the deficiency results in more time expended in development, an inconsistent presentation, or a lack of corporate identity in the finished product.

Review of Current Literature

The developer of the instructional materials may present solid content in a clear and methodical manner, but without knowledge of design and layout principles, the learning situation can be less positive. For example, poor screen design has been experimentally associated with lower completion rates and longer completion times (Szabo & Kanuka, 1999).

Many style guides in the form of texts or online documents have been published in recent years relating to the display of information on computer. These generally include a standard component of guidelines for text, graphics, colors, fonts, and animations (Deaton & Zuback, 1995; Lynch & Horton, 1997).

One category of style guide reflects guides that have been developed in response to a specific programming language. Lynch and Horton (1997) in the Yale C/AIM Web Style Guide provide suggested structures for HTML-based online documents. This is one of many style guides (Deaton & Zubak, 1995; Kidder & Harris, 1997) that is specific to a programming language based upon HTML, XGML and other markup languages.

The alternative to program language specific style guides are those that are generic in nature and address online delivery without reference to specific programming languages, platform or authoring tool (e.g., Naval Air Maintenance Group, 1997). A review of these guides finds that recommendations are made for most screen elements including fonts, colours, margins, placement of graphics, and animations.

Corporate-specific style guides contain specific guidelines for the development of online materials to meet the needs of individual corporations and be applied to all projects developed by the corporation. In addition to the base elements that make up the screen, the corporate style guide provides specific recommendations for the use of corporate logos, company specific terminology, acronyms, hyperlinks, etc.

In the academic world, selection of individuals to carry out the development of a CBT project often have as a primary requirement a background in instructional technology and curriculum development. The creators of the online documentation or the CBT materials for the corporate world often do not have formal qualifications in the development of online materials. The development of a style guide has the benefit of providing these individuals with suitable guidelines for the development of the materials.

Development and Maintenance of the Style Guide

The reasons for developing a corporate style guide include adding consistency to online documentation and CBT projects and providing guidelines for corporate usage of logos and terminology. The development of a style guide for the project illustrates a concern for quality and effectiveness in the development of the project. Adapting the staged process outlined by Woolever and Loeb (1994) for the development of the style guide for computer-based delivery projects would include examining the online documentation CBT development needs, the user groups, and the delivery technology, and then researching and defining the required screen elements. To this Hackos (1994) adds usability testing of the finished online product and regular updating of the recommendations in the style guide.

A Fortune 500 respondent located in Edmonton, Alberta indicated approximately 300 hours were spent in the initial development of a style guide for online documentation and CBT materials. An additional 20 hours a month was spent by the documentation and training team to regularly review and update the style guide.

Problem Statement and Research Methodology

The research conducted for this paper explored the hypothesis that few corporations currently developing computer-based training or online documentation have developed internal style guides relating to materials that are intended for online delivery.

Ten volunteers from the corporate training sector were solicited through the Vancouver Chapter of the International Society for Performance Improvement (ISPI), the Alberta Chapter of the Society of Technical Communication (STC) and through the bit.listserv.techwr-l newsgroup and completed the questionnaire via email, or telephone interview.

The survey asked the individual to select one specific project to refer to with respect to the survey. The questions on the survey were formulated to obtain information regarding: 1) the participant's background in online documentation and CBT development; 2) the scope and parameters of the specific project under consideration; 3) the existence of and extent of the use of a style guide for the specific project; 4) how screen elements were selected for the project; and 5) the impacts of having or not having a style guide in place at the start of the project.

Findings

Of the responses, six projects involved the creation of online documentation. Four projects involved the creation of CBT materials. In all cases, the participants were involved in the project from initial planning to implementation. Job titles were equally divided between those who classified themselves as instructional designers or technical communicators. Several individuals had project management responsibilities. Respondents were asked to classify their experience in their current position. In a number of cases the individuals worked as independent.

Two individuals were trained in a vocational/technical program (communications or urban planning), five attained the bachelor degree in English, and three achieved the graduate degree (two in curriculum design and one in instructional technology). Examination of the education backgrounds suggests that within the corporate world the need to have a documentation or CBT product delivered outweighs the requirement to have the most qualified individuals completing the work. Three respondents participated in the development of more than ten projects each, four of the respondents stated the project discussed in the survey was their first online project. Two individuals had completed two projects, and one individual had completed four projects.

Usability Testing

Usability testing identifies deficiencies existing in the projects prior to their release and is carried out with typical target population users to ensure that the materials are easy and efficient to use, understandable and achieve the desired goal. Only one online documentation project had a formal usability testing process that was carried out on a prototype. One of the CBT projects had informal reviews of the screen layout and structure that was carried out by the members of the development team. Of those projects that did not have usability testing processes in place, seven had reviews of content for validity by subject matter experts but none for screen structure or presentation elements. The most common reason for a lack of usability testing in the cases of the online documentation was the assumption that the defaults from the RoboHelp ™ authoring tool would be adequate. One project claimed that the corporate demands were such that the project had to be developed and put online as soon as possible. In this case, there was no allowance made for testing even after the projected was made available within the corporation.

Development Teams and Tools

Seven were developed with a team structure and three were developed by individuals. Five projects had the actual coding for the online documentation or CBT carried out by programmers, and all of these projects were developed in the team environment. In the remaining five projects, the instructional designer or technical communicator, whether part of a team or working individually, was also responsible for the coding to create the online system. In four cases out of the five from this later group, the coding was done with an authoring tool.

Use of Style Guides

Only four had projects that followed formal style guides; one was a general corporate style guide for both online and paper-based projects, and three were specific to online projects. With respect to length, the four guides were approximately 16, 40, 60, and 180 pages respectively. The most extensive guide was contributed by the Nasdaq 50 company and included sections for layout and stylistic elements (50 pages), as well as for word usage, grammar, and in-house terminology and acronyms. All four style guides contained guidelines for common structural elements such as font type, style, and size, screen margins, text and background colours, how to incorporate graphics, placement of text versus graphics on screen, and general screen layout. The shortest guide contained only guidelines for screen conventions and elements, and did not include guidelines for construction of text.

Impact of Style Guide Use

Overall, those projects that developed and used a style guide did not report significant revisions to screen elements after development had begun. In three cases, the style guide was adhered to and there were no revisions to screen elements after the project was underway or after implementation. One project that used a style guide reported approximately 15 days out of total development time of approximately 1,000 days was spent revising the navigational paths. However, in this case there was no modification necessary for the screen elements. In one corporation approximately 15 percent of the total time of two programmers who did the development of the HTML-based CBT system was spent in revisions to screen elements such as margins, fonts, and navigational elements. The revisions were due to the programmers' lack of adherence to the corporate style guide.

Six projects were completed without a style guide. Four were online system documentation. The remaining two projects which did not use a style guide were CBT projects. In both cases the development took place with a team of instructional designers who researched and developed content, and programmers who produced the HTML-based CBT products. Both projects reported a substantial amount of rework of the screen elements including font type, style, and size, background colour, placement of controls and buttons, size of graphics, animation of graphics, and screen transitions. Costly animations were removed after project implementation as they only increased file size and download times, while adding no real value.

One respondent reported the revisions to screen elements amounted to fifteen percent of the programmers' time, amounting to approximately 7.5 weeks of time during development and implementation. The other project without a style guide that did not use authoring tool defaults reported that approximately ten percent of the programmer's time was spend doing usability related revisions, or 4 days, $3,500 in cost.

Conclusions

The research explored the hypothesis that few organizations have developed internal style guides relating to materials that are intended for online delivery. Results indicate that \style guides in the corporate world for the development of online documentation and CBT materials is limited. The use of style guides in these projects results in a reduction in effort spent revising screen elements. This substantiates the findings of Allen (1995) that a lack of a style guide increases the development time of projects. In two projects that did not use a style guide, ten and fifteen percent of the revision time was required in the overall programming time. Four projects did not indicate that significant time was spent on revisions after implementation.

This research revealed a number of items related to the field of instructional technology that may be indicative of these projects in the corporate world. These include using individuals who have no academic background in instructional technology to develop online projects, a lack of usability testing for corporate online projects, and the unqualified acceptance of authoring tool defaults in the absence of any formalized style guide.

Only one project included a formal usability test due to corporate demands to complete the project and make it available; there was no time for formal testing at the completion of the development. Several projects initially undertook informal testing, but the testing was done by the project development team. This raises questions of impartiality and objectivity. Only one of ten projects included a testing phase. This lack of usability testing may indicate that some corporations view the documentation or CBT that accompany their products as a necessary component, but one where expenses can be saved as it is not the main product that a customer is purchasing.

This exploratory research has found that there are a great number of style guides available publicly, intended for general use and for specific purposes. Additionally, a number of corporations have developed their own in-house style guides with the intent of standardizing the development of and ensuring that there is consistency between online publications. However, there is a large percentage of corporations that do not follow a specific style guide, and allow the developers of online documentation and CBT projects the freedom to design based upon their personal preferences.

Abstract

Recognizing the recent and expected growth of e-learning, this paper explores the responsibilities of the e-teacher to excite students, develop a learning community, individualize the experience, provide meaningful feedback, provide adequate control and flexibility, and demonstrate expertise. The authors describe, based on their experience with e-learning, best practices that fulfill these responsibilities.

Introduction

Many reports point to exponential growth of online learning and teaching activities both in educational and corporate settings (Bonk and Essex 2000). This growth is due, in part, to advances in technology that have made e-learning possible. The advent of e-learning has revolutionized our thinking about teaching and learning.

However there are other reasons, aside from technology, which have contributed to the growth of e-learning. First, rapidly changing environments, technologies, a world market (to name just a few factors) demand that our workforce continually upgrade their skills. The anywhere and anytime flexibility provided by e-learning (Pantazis, 2002) make this imminently more possible; an organization can create a certification program, make it available to all of their supervisory personnel, and allow participants to complete the program according to their individual best schedule. This fosters both uniformity of learning and individual accommodation. Second, e-learning has the potential to narrow, if not eliminate, the skill gap that exists between homemakers (woman who are primary care givers of their families, stay-at-home-moms), disabled persons, older and working adults (whose formal education is out-of-date) and traditional college students. Thus, one can conclude that the growth in this area, although rapid, has not nearly reached its peak and will not plateau anytime soon.

Universities are well aware of this trend and most have implicitly or explicitly put pressure on their faculty to engage in online teaching. For most university instructors this is a new domain, one that offers many exciting challenges but also invokes much anxiety (Bonk and Essex 2000). Ideally, the translation of a traditional classroom class into an on-line modality is facilitated by a 'development team' in conjunction with the faculty member. However, the ideal is not always available and often the faculty member is both the creator of content *and* the developer of the modality. In this paper we will discuss our experiences and insights in online teaching and share some of our best practices. Both authors have taught many web-enabled courses (either entirely online or in a blended setting). The courses taught span a wide range of domains from quantitative subjects (such as Management Science/Operations Research) to more qualitative subject matters (such as Communication and Interpersonal Skills). Through our experience, we have developed/discovered many strategies that help e-learners succeed as well as make e-teaching manageable and rewarding for us.

E-Teaching Strategies

A common misconception about e-learning is that all the teacher needs to do is to create a web-page. Effective e-teaching is much more than putting your notes, problem solutions, and assignments to a web-site. E-learning also goes beyond simply asking your students to work their way through an interactive CD-ROM. These approaches simply replace the medium of a traditional "correspondence course" from paper and postage to digital format. On the other hand, effective e-learning requires the creation and promotion of a rich, collaborative, flexible, and exciting learning environment. The challenge is to do all this in absence of face-to-face interaction.

Faculty members find that some of their tried and true approaches do not work in this new medium; we need new 'tricks of the trade'. Specifically, we need new ways of creating excitement within the student, we need new approaches to developing the learning community, we need to individualize the learning experience, we need to develop new ways of providing effective feedback, and we need to provide structure and control while maintaining the flexibility that makes e-learning so attractive.

Exciting the Students:

BEST COPY AVAILABLE

Most traditional classroom instructors use their personality to make the *topic content* exciting, memorable, and applicable. They use the interpersonal connection with the students to entice the students' interest. They use non-verbal as well as verbal cues to interpret student distress, interest, confusion, and boredom. The richness of the face-to-face modality allows the instructor to use those inputs from students to spontaneously revise their lecture, to add an example, to ask a question, to interpose an experiential exercise, to alter the timing, tone, sequence, cadence of the lecture, and sometimes to use humor to engage the students.

The technology of e-learning removes many of these feedback cues given by the students. Further, the interactions and discussions that have been habitually used to create a *culture of effective learning* need revision.

In an online environment, we can arouse student's emotion about a topic by incorporating real-life examples into the process – we can reinforce the connection between theory and practice, between class and work. Specifically it is effective to ask students to post comments on a discussion board and also to *make them* relate topics in the news to the content being used.

Well-designed assignments can also be used to foster enthusiasm and make the content meaningful. An assignment that asks the student to "assess" their own organization is very useful for them and it is content-intriguing. Assigning students to "actively listen" to their spouses/significant others (some have completed this assignment with their moms) for 20 minutes is not only an effective way of making material relevant, it also endears the teacher to the spouses/significant others.

Creating a Community:

The greatest drawback of on-line education is, by far, the sense of isolation experienced by the students. On-line students frequently comment that they miss the synergy generated in traditional classes. While the best lecture and content organization will not prevent this, it is possible to create and support a collegial atmosphere. Our goal was to create a culture that engaged, motivated, inspired, and connected students – we wanted them to experience membership in a true learning community. Out best-practices include:

- Contact the students as soon as possible. In our case, since the course web-site is not available until the official start of semester, we contact our students in advance with a letter using "old-technology" of paper and postage stamp. This prepares the students for early engagement.

- Conduct a chat room during the first week of class. Assign students to specific times, a half hour is enough, so they get familiar with the how-tos of 'chatting' and they interact with some of their classmates. It is a good idea to have additional chat rooms (change the assigned mix of individuals) later in the term to enlarge their 'community'.

- Arrange for a face-to-face session if possible. We arrange for an "on-campus" orientation session for the students. [For those who cannot attend, we arrange for a phone conversation.] This single session has been very effective in relaxing the students and promoting a strong student-to-student and student-to -instructor bonding.

- Create an on-line "get-to-know-me" session. Introduce yourself and provide relevant information about yourself, include some of your interests/hobbies. This will allow the student to get to know you better and gain confidence in your expertise. Ask everyone else to do the same. This helps students to get to know each other too. It is also advantageous to have a section in your on-line syllabus that describes the teacher; I label mine – "About your instructor". This includes pet peeves (on-line assignments that do not include the student's name), expectations about communication (label your email), and preference for theory-based learning.

- Recognize and rescue the lost students. The fact of the matter is that some students DO feel lost. Whether they are insecure about the technology, they are less disciplined than they should be, or they have simply fallen behind/lost momentum without the face-to-face reinforcement, they need to be rescued. Technology should not be allowed to be a barrier to their successful participation. A brief assessment of the students' technical skill level at the beginning of class will identify vulnerable students. Rescue, when needed, can be achieved by providing additional help with those who may need help with technology; we are fortunate to have a 'computer consultant' who will work with them and our IT support department will also provide telephone coaching. On an on-going basis, it requires that instructors pay attention to patterns and quality of output of each student and that they get in-touch with a student when his/her communication or the quality of work starts to diminish.

- Promote interaction. Research has identified four types of interactions: learner-teacher, learner-content, learner-learner, and leaner-interface interaction (Hillman 1994). The course design should provide an opportunity for all four types. Chat rooms and Discussion boards enable these interactions and help promote a sense of community among the members of the class. Making team assignments also facilitates (forces) a sense of community. The technology exists that makes it easy to create chat rooms, email lists, and other communication possibilities for select memberships. However all interactions need not, and one could argue, should not, be in a form that requires the student to be in front of the computer. E-learning provides a unique opportunity for the instructor and the student to *expand* the learning community. When students are asked to examine their organization, to describe their work relationships, or to videotape a work presentation, the learning community expands to include colleagues, bosses, and family members (at least). In short, the activity involves others and the impact of the education grows. It has been gratifying to note the (more frequent) occasions when students have said "I was talking with my boss" or "I asked the people I work with…".

Individualizing the Learning Experience:

BEST COPY AVAILABLE

When developing content and activities for your course, keep in mind that students learn differently, and you must include activities that will appeal to a wide range of learning styles. Kolb (1976) suggests that people prefer to learn in one of four different ways. Some people prefer to learn through concrete experiences, others prefer observation and reflection, others prefer the formation of abstract concepts and generalizations, and still others prefer testing implications of concepts in new situations.

Many instructors see their role as the content provider, preparing and presenting 'lecture notes'; this would appeal to students who learn best through 'forming abstract concepts and generalizations'. However, even lecture notes can be modified so that they appeal to a larger group of learners. For example, in an Operations Management class when teaching a topic that requires a lot of mathematical manipulation to demonstrate a concept, students can click on various models to start an animation that will take them through the steps. However, if the student grasps the topic by just reading he/she doesn't have to go through the animation. The key is to design the notes in such a way that students have control over how to receive the information.

For the student who prefers to learn through 'concrete experience' or 'observation and reflection', appropriate links can be provided so the student can take a "Virtual Plant Tour". Some companies have live cams that stream video over the Internet; this allows the students to see how everything is being done. Other companies provide high quality animation of their processes. These "plant-tours " engage the learner who has a more tactical style of learning.

For the student who prefers to learn through 'testing implications in new situations', assignments must relate the theoretical to the practical. Creating a real business plan has this result; acting as a (would-be) consultant to one's own organization makes the material relevant in a new situation; and solving a school districting problem in an Operation's Management class uses this approach well.

Internet provides a rich environment for learning and it is important to incorporate this richness into the learning process.

Providing Meaningful Feedback:

Rich feedback is as important to the e-learner as it is to the traditional student - in some ways, perhaps more so. Since they do not have face-to-face contact with the teacher, the teacher's reactions to their work carry more weight and are used more heavily by the student to judge their competence and their sense of mastery of the material. It also keeps students actively engaged in the class; providing timely feedback is an important factor for helping students remain active in the process (Bischoff 2000). For effective teaching, it is important to provide feedback in a timely fashion and to provide it often.

Instructors should strive to provide feedback as swiftly as possible and it should be feedback that is useful to the student (i.e. not just a grade). Certain e-learning technologies make is easier than others to provide comments on student's work. When there is a 'feedback box' (e-college), use it to comment; where it is possible to type in your comments on a paper (in a different colored type), do that. When it is NOT easy to give feedback, this author has printed the material, written comments in the margin, and returned the material via snail mail – this extra effort was greatly appreciated by the students. It is also possible to simply email each student with your comments or reactions on their work, or engage in a chat room or an individualized threaded discussion to discuss the merits of their work.

It should be understood that giving students useful feedback is very time-consuming in e-learning; it is also one of the key variables in making the learning worthwhile and permanent. It is a very important element in establishing the learning environment and maintaining a learning community. Prompt, thorough, and thoughtful feedback not only allows learners to know how they are doing, it also keeps them aware of teacher's presence.

Initiating Structure and Control:

One of the true benefits of e-learning is the fact that it is self-paced and therefore flexible to the learner's needs. However, one of the dilemmas for the teacher is *howmuch* control to give to the learners. We experimented with a completely self-paced curriculum and, while it was not a total disaster, it certainly got out of hand. Some of the students procrastinated, some sped ahead through the course, and some paced themselves and took the material one module at a time - the instructor ended up grading all 7 modules at the same time and the learning community was seriously compromised.

We have found that paced systems work well; this is also supported by research (Vrasidus 2000). A course that is broken into individual modules with clear objectives, structure, and assignments is the most viable. The pace at which the modules are opened (and closed) to learners is controlled by the instructor and all activities within a module must be completed by a date provided by the instructor. [In the communications class, students are automatically granted a week's grace period past any given due date – while this is cumbersome to the instructor, it does acknowledge that the students travel a lot and their schedules are not as predictable as they (or the instructor) would like.] This allows some flexibility; while at the same time it encourages students to interact (via chat room or threaded discussion) as they deal with common curriculum content (i.e. they are all reading and reacting to Albert Ellis's fallacies during the same week).

Another way of giving some control to learners is by allowing them to choose their activities. In one of the courses taught, we gave the students a "superset" (a smorgasbord) of activities to choose from, each activity was assigned a certain number of points (more points for more complex activities), and students were given the point system used for assigning letter grades. Based on their learning goals, intellectual interest, and commitment to grade point, students then chose which activities they would complete. In essence, they created their own portfolio of assignments. This course set-up has been offered several times and receives very positive feedback from the students.

Students experience greater control when assignments are easy to manage. Assignments should be easy to find, easy to follow and easy to interpret. Even though, in an e-learning environment, students can do their work anywhere/any time, we have found that providing a

BEST COPY AVAILABLE

predictable pattern is an attractive option for our students. If you have an entire curriculum delivered by e-learning, it is a good idea for all faculty members to use the same style of syllabus, to have their assignments in the same place, and to coordinate their activities. For example, in our cohort mixed-mode program, students take two courses simultaneously – one instructor requires homework on Mondays, the other instructor requires homework on Thursdays. It is also advantageous to create standard operating procedures, i.e. all homework assignments are to be posted in the 'drop box" (Blackboard), all 'announcements' will be available for a 2 week period, chat rooms will not have over 10 persons at a time, etc. This routinizing is helpful to the students and eliminates the need for each instructor to re-create a wheel.

Proving your Expertise:

In the traditional classroom, instructors often share their experiences as supplemental examples to their lecture. E-learning lecture notes are often more sterile than live lectures so some of the personality, expertise, and experience of the instructor is not as obvious. Instructors need to find ways by which to share their expertise and demonstrate their professional contributions. Using chat rooms to chat about specific topics (not as office hours), contributing to threaded discussions, asking provocative questions, drawing attention (via announcements) to relevant news items, drawing attention to hot topics and emerging trends are all ways of making you a multifaceted person in their eyes. The quality of feedback you provide to the students is another way of communicating your expertise.

Conclusion

E-learning exist because technology enables it to and because it fills a need on the educational landscape. It would be a mistake for educators to think that this new modality could take their place; that by itself, a technology could create and maintain a learning environment. That part of education still belongs to the teacher. It is still the responsibility (and for most of us the joy) of the teacher to excite the student, to develop the learning community, to provide structure to the learning, to show off our expertise, to value the individual learner, and to give feedback that enables the student to grow. Some of the techniques needed for these tasks in e-learning are completely new, some are a slight adaptation from a traditional approach, and some are essentially the same as those employed in the traditional classroom. This paper suggested and highlighted a few new ideas and some variations on older approaches that have worked for the authors.

Web-based Supplementary Material to Complement Classroom Teaching - A Case Study

Toshitaka TAMURA, Shinichi FUJITA, Akiko SWAN, Toshiko HOSAKA, Ming YIN, Seinosuke NARITA
Waseda University
3-4-1, Okubo, Shinjuku-ku, Tokyo, Japan
tamura@moegi.waseda.jp

Abstract: The authors are developing an effective, practical computer-aided instruction (CAI) system for use in class, consisting of three parts: web-based teaching material, a learning evaluation and management system, and a support system for editing the web-based teaching material. The web-based teaching material is based on the textbook "Total Japanese", which is used to teach Japanese as a foreign language. It is important that any CAI system used in class is designed to suit individual styles of teaching, since each teacher has their own approach. When the authors began to develop a suitable CAI system using existing courseware authoring tools, the authors found many problems, because these tools were not designed for use by teachers. This paper discusses the need for teachers and engineers to co-operate in the design and development of better CAI systems.

1. Introduction

There is an increasing demand among teachers for computer-aided instruction (CAI) systems that make use of advanced information technology. Such systems are expected to improve student motivation and understanding. To meet this demand, a number of support systems have been developed to facilitate the design of CAI systems. The authors have been developing a CAI system to teach mastery of the Japanese language in accompaniment with the textbook "Total Japanese", which is used in Japanese language classes.

The authors soon found that courseware authoring tools such as WebCT [3] and HotPotatoes [4] did not meet teachers' needs. These tools are designed for use by many users, but a CAI system should be customized to meet individual teachers' specific needs. Moreover, a customized CAI system improves speed, cost, and ease of use [5].

Involving teachers in the development of CAI systems increases the likelihood of developing practical systems, since teachers know what is needed and are aware of effective ways of teaching. However, they may not know whether it is possible to design a system with the capabilities that they desire, given the present state of information technology. Consequently, they may be unable to complete the system until what they want becomes available, even if they manage to conceptualize it. By contrast, if engineers develop a CAI system on their own, they may produce a novel, advanced system because they are aware of the available technology, but it might not be what active teachers really want. Therefore, The authors concluded that teachers and engineers should co-operate in order to develop an effective CAI system for classroom use. The authors tried to make the best use of current information technology to produce an effective and practical CAI system to assist in teaching Japanese.

2.The CAI system

In designing the details of the system, it is important that teachers and engineers work together. Teachers have many ideas about functions that they would like to incorporate in the CAI system, but are not likely to know whether they can be realized given the present technology. By contrast, it will be necessary for engineers to conceptualize these functions and then produce the actual interface. The engineers will have to tell the teachers what functions are possible. In addition, they must be able to suggest alternatives for the functions that they cannot realize. The teachers will need to tell the engineers specifics of the design, such as where the answer field or buttons should be in the teaching material and what kind of images to display.

(1) Partial development of the system

The CAI system is still in the process of development; the authors are currently testing the parts that have already been completed. This has been made possible by dividing the entire system into several components, so that the authors can analyze, design, develop, and test each component. This is the "round trip" model of development, which is a flexible development style. In this way, the authors can obtain feedback on the system and teaching material from teachers and students almost immediately, allowing us to make improvements at any time.

(2) Sharing information

Feedback from teachers and students is via e-mail and at meetings held at least once a month. In addition, any problem that arises in development is reported to all the teachers and engineers via e-mail, even if it is only small. In this way, the authors can constantly confirm whether there are any differences between the teachers' requirements and the system's abilities while the system is still under development.

(3) The system suits classes

In order to make an effective system, it is necessary that the system developed is as close to teachers' requirements as possible. It is important to determine which functions in the system are appropriate. For instance, useful user interfaces are needed, while a CAI system that incorporates AI (artificial intelligence) functions is unnecessary, because teachers fill that role in the classroom.

3. System outline

Our system is an integrated CAI system that consists of three components:

1. Web-based teaching material
2. A learning evaluation and management system
3. An editing support system

Using these components, teachers can edit the teaching material and manage their students' progress. This system is a web-based educational system. Only teachers have access to the editing support system.

(1) Web-based teaching material

The teaching material is based on the textbook "Total Japanese" published by the Center for International Education at Waseda University. This textbook is intended for foreign students studying in Japan, but students studying in universities all over the world use "Total Japanese" as a Japanese language textbook. The students are expected to develop a comprehensive understanding of the rules of conversation, reading, and writing. The authors used Macromedia Director 8J as the authoring software to create this material.

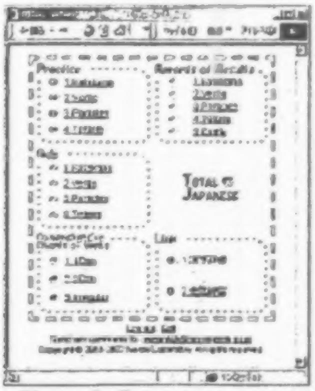

Figure 2. Top menu.

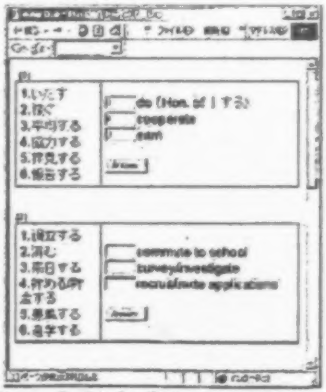

Figure 3. Verbs Quiz.

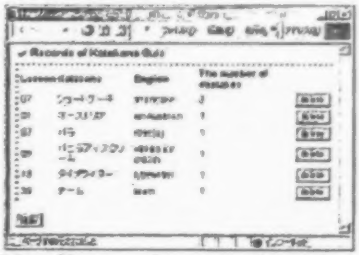

Figure 4. List of incorrectly answered questions.

BEST COPY AVAILABLE

(2) The learning evaluation and management system

In self-directed learning, development of a system and material that allow the student to recognize and solve individual problems is indispensable. Such a system must analyze each student's weaknesses and their leaning progress, so that teachers can provide more effective lessons. This system allows teachers and students to determine the following:

a. The questions answered incorrectly by each student;
b. The percentage of questions answered correctly and examples of wrong answers (Figure 5); and
c. The login history of each user.

Each student can review their list of incorrectly answered questions (Figure 4). This function displays the lesson number, each question and answer, and the number of mistakes, allowing students to recognize problem areas. They can also study the questions that they have answered incorrectly by pushing the "Review" button. When students think that they have mastered a question, they can delete it from their lists.

(3) The editing support system

Teachers can edit the teaching material data in accordance with students' abilities. Teachers know how well the students understand the textbook from the data obtained from the learning evaluation and management system. If most students don't understand the content of a lesson or part of a lesson, the teacher can change the questions or answers. This is a very handy function if it can be done easily. The authors use Microsoft Access 2000 as the database and Active Server Pages (ASP below) as the Web application technology. The authors constructed the system so that teachers can edit the database on the server from their browser, using ASP. In this way, teachers can operate the database on the Internet, simply and without expertise. This is a versatile system that allows teachers to customize the material (Figure 6).

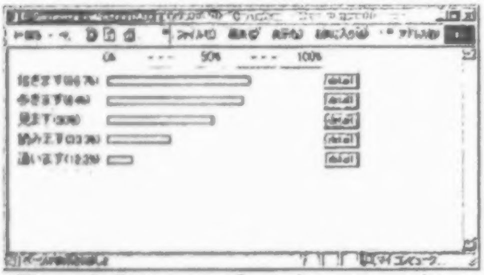

Figure 5. Percentage of questions answered correctly

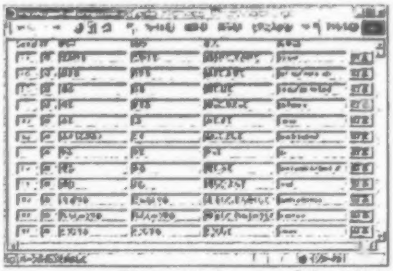

Figure 6. Image of the editing support system

4. Evaluation

Students studying at the Center for International Education at Waseda University, Japan have been learning Japanese using this system. On January 1st 2002, 117 students were registered on this system. The authors surveyed 16 students and asked them how the system had contributed to their study of Japanese. The response to each item on the survey was given on a scale of 1 to 5. The survey questions and results are listed in Table 1.

The items in the survey were based on the ARCS [6] model, which is considered a barometer of student motivation. The ARCS model consists of four factors: Attention (Q.1 - Q.2), Relevance (Q.3 – Q.5), Confidence (Q.6 – Q.7), and Satisfaction (Q.8 – Q.9). The first two questions (Attention) show that most of the students find this system attractive. For Relevance, there were some negative responses to Q.3 and Q.5, but the best response in the survey was to Q.4 "Relevance to learning Japanese". Fifteen (94%) students found this material valuable and that the system was very relevant to their learning Japanese. The material used was based on the teachers' input and this result confirmed its effectiveness. The responses to the Confidence questions indicate the high quality of the system and teaching material. Nevertheless, much still needs to be done to change students' stereotypical views of Japanese language. The Satisfaction responses show that this system was valued for the most part, although some improvements could be made.

	Question	Score
Q.1	Studying on the Total Japanese website is: 1. Not interesting at all – 5. Very interesting	3.875
Q.2	The Total Japanese supplementary materials are: 1. Not interesting at all – 5. Very interesting	3.875
Q.3	Do the TJ supplementary materials motivate you to study on your own? 1. Not at all – 5. Definitely	3.25
Q.4	Studying the Total Japanese supplementary material: 1. Is not relevant to your learning Japanese. – 5. Is very relevant to your learning Japanese.	4.3125
Q.5	Studying the Total Japanese supplementary material: 1. Is not relevant to your daily life in Japan. – 5. Is very relevant to your daily life in Japan.	3.75
Q.6	Using the Total Japanese supplementary material is: 1. Not rewarding at all – 5. Very rewarding	3.75
Q.7	After using the supplementary material, you came to feel that learning Japanese is: 1. Very difficult – 5. Very easy	3.0
Q.8	Using the supplementary material is: 1. Very boring – 5. Very enjoyable	3.6875
Q.9	Using the supplementary material is: 1. Totally unsatisfactory – 5. Very satisfactory	3.6875
	Average	3.6875

Table 1. The questions used in the student survey

5. Conclusion

The authors have developed this CAI system through the joint efforts of teachers and engineers. As the survey shows, the authors are developing a practical CAI system that satisfies teachers and helps with difficulties in teaching Japanese, as determined by active teachers. This system is still under development. The authors plan to enhance the teaching material so that the system can be used by students at many different levels of learning. In addition, the authors are also thinking about enabling student access to the system via cell phone or PDA (personal digital assistants), so that they can use this system anywhere, anytime. Finally, to incorporate CSCL (computer-supported cooperative learning) in this system, the authors will allow students to input quizzes.

Abstract: The National University Of Singapore School of Business and the Centre for Instructional Technology have jointly design and developed a student online share trading system. The system enables students working in groups to select a portfolio of shares from those listed in the Stock Exchange of Singapore and track their portfolio value on a daily basis. The main purpose of the system is to simulate a stock market environment where students can invest in real stocks and track real prices. Students have gaps in their knowledge in terms of the practical application of the Capital Asset Pricing Model to real world companies, a trading system will allow students to apply what they have learnt and determine if the theories are applicable in real life. The system is linked to a forum and course materials found on the learning management system of the university. This paper describes the system, reports on students' feedback, discusses system weaknesses and future developments.

Introduction

The National University of Singapore, School of Business, Corporate Finance course (BZ3301) aims to provide students with in-depth understanding of how finance managers utilize and steward their financial resources to achieve maximum returns to shareholders. Students are exposed to key financial issues like risk and return trade-off, how the equity market works, the various financial analysis tools and capital structure of firms. The course covers both conceptual issues relating to the management of financial resources and the practical applications of those theories in a real business setting.

Students' Term Projects

Students have to complete two projects in this course. The first project is the application of the capital asset pricing model (CAPM) in the selection of stocks which students can invest in. This first project provides a bridge between theory and practice. A second project tests the analytical skills of the students as they apply the theories and knowledge gained in the course to a case study.

The online trading system and the term project.

The first project resulted in the development of an online trading system with the purpose of integrating IT into knowledge delivery to the students. Traditionally, CAPM has been taught as a mathematical model for the pricing of stocks. Students are not able to connect the theories with real world practice because it is not clear if the theory really works in the real world. Before using the online trading system, students analyze the stocks by applying the theories they learnt in class, they then proceed to apply their knowledge by selecting stocks in a created stock market environment.

Real world, internet based, action learning projects stimulate interest and motivates students. A hands-on approach to learning investment strategies is more meaningful than traditional teaching methods thus resulting in greater retention of new knowledge. (Curcio, 2000). The idea of online trading is not new. Several universities around the world have simulated trading rooms. Many high school students in the US are familiar with online trading. Several companies provide free online trading services to students. Such activities motivate students to monitor current news and market trends, apply math skills and stimulate interest in economics. (Lopus & Placone 2002). The National University of Singapore decided to build its own system because the trading rules are unique and customized to meet course project requirements. Moreover, the lecturers wanted students to analyze and invest in stocks listed on the Stock Exchange of Singapore rather than other exchanges.

Three lecturers, one hundred and sixty students from five lecture groups, divided into twenty-eight project groups are currently involved in this project. Each group of student is given an initial virtual amount of S$100,000 to invest in equity stocks listed in the main board of the Stock Exchange of Singapore. Each group must select 10 companies to invest this money. Students log into the system and select the stocks. The program tracks daily price movements of stocks and updates the groups' portfolio value on a daily basis. Students are able to monitor their portfolio performance in an accurate, secure and reliable environment. Students can also view the performance of other groups. They are however not able to view the detailed portfolios of the other groups. They are encouraged to discuss and share their group's portfolio performance in the forum. The better groups give pointers to those groups who are not performing as well and students can defend their choice of stock pickings. It is hoped that this will encourage communication and sharing between the different lecture groups. This project propagates knowledge assimilation and learning since students can observe the results of their decisions as the companies which they analyzed and trade in are real companies. In addition, the competitive pressure between groups' performance creates excitement so as to deliver maximum learning impact and the congruence between theory and real world practice. The winning team receives a lunch treat from the lecturers.

The design of the trading system: Administrators' section

The administrator's section allows the instructor to set variables such as start and end date of the activity, initial capital outlay, number of companies to select, deadline for making a final buying decision, view all groups' detailed portfolio, view a summary of group performance and view stock listings. The administrator can also access the course materials and discussion forum created using the university's learning management system.

Registration of students

Students are currently registered by the programmer and put in groups. Students are registered based on their university user ID and password. However, in the next phase of the project, the instructors will be able to register student groups from the administrator's section and this system will be able to extract student group information from the university's learning management system.

Students' section

Students log into the website using their university user id and password. They have already been registered into their respective groups. From the students' section, they can purchase stocks, track their portfolio over the period of the project, view details of their group portfolio, view a summary of other groups' portfolio, access the course forum and course materials and view stock listings. Note that students are not able to view detailed portfolios of other groups. Due to certain constraints which are discussed later in this paper and course project requirements, students are not allowed to buy and sell stocks during the lifetime of the project. Students have access to the forum and course materials on the university's LMS.

Data source and technology

Stock prices from the stock exchange of Singapore main board are supplied by Datastream. They reflect the previous day's closing price. Data from Datastream is extracted into an Excel spreadsheet, rearranged and transferred to an Access database. Since Datastream does not supply real time data, the prices are one day behind. ASP programs are written to post portfolio prices online based on student groups.

Students' reaction and feedback

142 student survey forms where collected in an attempt to evaluate students' reaction to this new system. The survey measured students' perception about the usefulness of the system in bridging the gap between theory and practice.

72.5% of students agreed that they are more enthusiastic about their project when they use the trading system. 85.9% thought that such a trading system is necessary in the course. 83.8% of students agreed that this is a more convenient way of tracking portfolio performance. In the past, students recorded each day's profit or loss on paper. The method is inefficient because it was prone to human error and deliberate mistakes were possible. 85.2% agreed that the prices and numbers were reported accurately. The inaccuracies were due to bug fixes during the first week when the project was launched. Technical problems have since been rectified. It is interesting that 76% of students felt it is important for their team to select the right stocks because group performances are now made public through the system. 68% of students felt motivated to further analyze the movement of certain stock prices while 60% of students agreed that such a system gives them an opportunity to apply the theories they learnt. Since the groups are not able to see the details of other groups' portfolios, 79% of students were curious about the stock pickings of the winning team. It is not surprising that only 30% of students found the forum useful because the instructors did not encourage the use of the forum. Despite curiosity about other group's detailed portfolio, only 19% of students discussed price movements and exchanged views with students from other groups.

Students wanted the system to update prices by the minute instead of daily. They want to be able to buy and sell stocks during the project. One student requested for charting features for portfolio performances of various groups.

System weaknesses

All system weaknesses were identified in the student feedback. Prices are updated on a daily basis instead of real time because Datastream does not supply real time data like Reuters or Bloomberg. Datastream reports previous day's closing prices. It should be emphasized that the corporate finance course aims to train finance managers and not speculators, students are expected to analyze the medium and long term financial health of a company. Minute by minute spot trading or speculation is discouraged. Students must be able to select the right shares, hold these shares over a period of time and make a profit. Therefore, real time data is actually not a necessity. However, to simulate the real world, students should be allowed to buy and sell during the project. Without real time data, students cannot be allowed to buy and sell in between the project as they can obtain before hand information and trade accordingly to make a profit.

Second phase of the project

The second phase of the project will be launched in the new term starting July 2002. There will be charting features where students will view a line graph of their portfolio performance in comparison with other groups' performance. This will make comparison much easier and create a bigger impact. To make the system more realistic, a commission rate, to be set by the instructor will be included in the calculation of profit and loss. Student registration and groupings will be managed by the instructors and at this point, the developers are seriously considering using real time data so that students can buy and sell stocks during the project. The design of the trading system follows closely those designed and developed in the real world. Students will be encouraged to use the discussion forum and discuss price movements with other groups.

In the long run, it is hoped that real time bid and asking prices can be used. Project guidelines must discourage speculation by setting the maximum number of buying and selling transactions within the project period. Students should also defend these actions and all transactions should be tracked.

Conclusion

In addition to providing market reports and analysis, the internet makes it possible for students to have direct hands on experience with financial markets. This encourages students to connect economic concepts to the real world. When combined with active learning-teaching strategies, students will find corporate finance more relevant and this will in turn improve learning. (Scott, 1999). The results of the survey show that students are kept motivated and interested in the course. Most students felt that such a project is necessary and wanted a real time trading system where they can buy and sell shares anytime. Improvements will be made in the second phase of the project to address some system weaknesses. The team will work towards developing an environment that would give students a feel of real time online trading and at the same time meet the unique teaching and learning requirements of the course.

Abstract: The National University of Singapore, Centre for Instructional Technology implemented a campus wide pilot project to test the use of a computer mediated communications tool intended for students' project collaboration. The application known as Groove v1.3 was made available for download. The tool was widely publicized as a virtual space for students to discuss their term projects. The project team also identified two focus groups of students whose instructors agreed to participate in the study. Students found the initial registration and logging on into Groove difficult. The tool was selected based on features such as, a user friendly interface and a full set of features which allowed for full team collaboration. However, the team did not realize that the initial registration of group members into the shared space could cause such difficulties. This article is a report on the pilot project and lessons learnt from it.

Introduction

In January of 2002, The National University of Singapore, Centre for Instructional Technology implemented a trial version of Groove, a peer to peer networked computer mediated communications tool. The purpose of this tool was to facilitate student virtual project collaborations. An evaluation was designed to determine if students benefited from the use of this tool and to determine its usability. The trial uses the free version of Groove 1.3. The university would decide whether to purchase licenses after this trial. All features of a CMC application are available in the trial version except for server support and roles management. The application was selected because of its peer to peer technology, complete set of collaborative features and friendly user interface.

Implementation

Groove.exe was placed on a website for students to download. The website had online tutorials, a self help section and a forum. Groove was very well publicized across campus as a virtual space for peer project collaborations. The team did not foresee the need to conduct extensive training because our students are known to be tech savvy. Faculty members were not expected to be involved in this project because this was a students' project collaboration tool.

Focus groups.

A part time MBA class consisting of eighteen students and an undergraduate Finance class of thirty students were identified as focus groups. There was training, free installation CDs, round the clock help via telephone or email and the lecturers agreed to be involved in group discussions.

The MBA focus group attended a 3 hour hands-on training session in a laboratory on-campus. The class was made up of working professionals and some international students. During the training, students created a shared space for their class. While working from their own home computers, they encountered difficulties in entering that shared project space using the same account they created during class. The concept of creating a shared space and inviting group members into the space was alien to many. The users did not like the practice of using a diskette to store log in information when logging in using another computer. Some users could not remember their passwords. In order for invitations to the shared space to be successful, at least one computer with the shared space must be active. If a student is trying to invite another, both students must be online. This created problems as not all group members are online at the same time. The logging-in interface of the application caused confusion: If a different computer is used, both new and existing users have to click on "New Account" in order to log in. The lecturer withdrew from the project. She found the tool unnecessary. The undergraduate focus group did not have any incentive to use the tool because by then, the lecturer of that class was no longer keen on participating in the project. He also did not see the need of such a tool. Initially, the team had designed an elaborate evaluation study to collect data from the two focus groups. However, due to the failure of these groups to get started with Groove, the evaluation was not carried out. A separate survey was designed to collect data from the non focus group.

Non focus groups

About 400 students out of an enrollment of 28,000 downloaded Groove on their own initiative during the trial period from January to April 2002. Only 12 feedback forms were received from those who successfully downloaded, installed and used the application. These 12 students had no serious complaints about the tool although one student who collaborated with his peer in India reported that the network speed was slow over long distances. These students were able to use the tool for project collaboration. All are students from technical disciplines. There were 3 women out of the 12. Six other students and 1 faculty member emailed the team to complain about technical problems. The faculty member from the School of Computing thought that the LMS of the university could serve his purpose because it was already widely used. Students are familiar with the interface of the LMS. Students did not know how the shared space in Groove worked. 56k modem users complained that the 17.7MB application is impossible to download. They gave up after waiting for more than half an hour. Some students complained they had no friends to collaborate with since their friends did not successfully install Groove. One user complained that the applications slowed her computer. There was no support from Groove.net in this part of the world. The university decided not to purchase Groove but to enhance the LMS for online project collaborations.

Lessons learnt

When selecting a CMC tool for group collaboration, we need to take into consideration the process of group member registration in addition to the standard set of tools such as file sharing, applications sharing, forum etc. While Groove has an easy to use interface and a full set of features, the registration process was not easily understood by most people. First time users need intensive training and technical support. "Even if the software is relatively simple to install and use, and is accompanied by a good clear manual, many students (and tutors) will still need additional help in getting on-line for the first time." (Bates, 1995).

Faculty members must be involved in encouraging the use of such a tool because when left on their own, students from non technical disciplines will be less likely to use such a tool than those in the technical discipline. From our experience, this problem arose because the 17.7 MB application was not easy to download, install and use. Students from technical disciplines were more willing to spend time to make the application work. There is indication that without faculty push, there will be more male users than female users. The small number of response in our pilot study makes it difficult to generalize this possibility, but it is consistent with the widely held believe that CMC has been a male dominated domain. (Savicki, V. 1996)

Student and staff training are necessary because online collaboration of projects is not a common practice in Singapore and the idea requires a paradigm shift. Learning culture favors highly structured instructor lead, face to face lectures. (Lamb. 2002) Singapore is about 632 square kilometers in area and it has an excellent transportation infrastructure. Hence, travel and distance have never been an issue for most people. This was why some students and staff did not see the need for the tool. Students and staff must be shown the potential benefits of online collaborations both within Singapore and across borders. The implementation must be guided by pedagogy. A demonstration of features and how they can enhance peer project collaborations is needed.

The vendor should be involved in user support and be willing to customize to the needs of the university. The lack of vendor participation and support is the main reason why the university decided not to purchase licenses for the application.

A CMC tool should be selected based on its ability to meet learner needs and not because it employs some cutting edge technology such as peer to peer networks. If a LMS is available and widely used in the university, there should be integration between the LMS and the CMC software. Students and faculty should only use a single UserID and password to access the LMS and the CMC tool. In our experience, users did not understand why a separate application should be created when the chat room of the LMS can be developed to meet such needs.

Future Plans

The team is now working to enhance the LMS chat features to support web based virtual group collaborations. In addition to the standard collaboration features, the new application, when completed will be an integral part of the university's LMS. Students will be able to group themselves easily because information is extracted from the university's main registration database. Students can use their existing UserIDs and Passwords. Administrators have full control over the server and log files. Faculty members can also group students and visit the groups. Both staff and students can continue to work in a virtual environment which is familiar to all. Moreover, students are not likely to use the application for leisure chat or social activities since the university is able to track usage. The team remains very positive that our student population will be receptive to the new technology and the new idea of virtual teams. Given the right tools, some encouragement and training, students will discuss projects online.

Effects of Collaborative and e-Learning on Skill Acquisition and Retention for Computer-based Cognitive Tasks

Kuo-Hao Tang
Department of Industrial Engineering
Feng Chia University
Taiwan
khtang@fcu.edu.tw.

Abstract: Based on a training program using a production system simulation software designed for the Theory of Constraint (TOC), the effects of collaborative training and after-training feedback representation method on skill acquisition and skill retention are investigated. An experiment with two training protocol, individual and triplet; two methods to present after-training lecture, face-to-face with the instructor and digitized video image; and three skill retention levels, immediately upon the completion of the training, after one week, and after one month were conducted. The results show that training protocol affects both training performance and skill retention ($p<0.01$) while methods to present after-training lecture affect training performance ($p<0.05$). In compared to the traditional face-to-face approach, the e-learning approach that conveying lecture materials solely through digitized video and slides without any post processing, not only decreases participants' attention but also reduces the time of eye contact between instructor and trainees.

Introduction

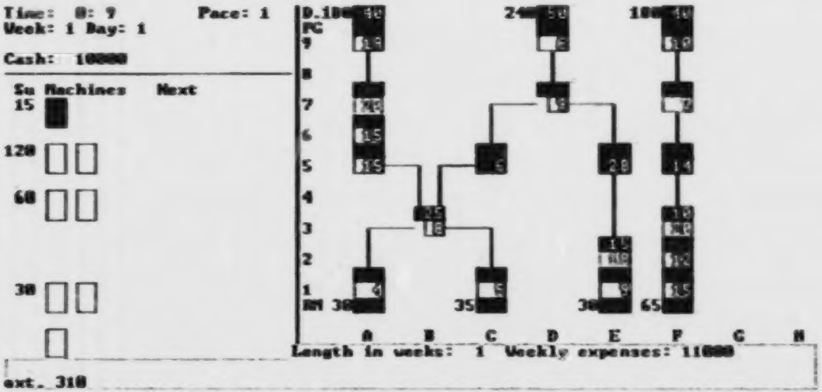
In the knowledge economic epoch, the lifelong learning through Internet or computer-based training programs has become an important learning means in many higher education institutes and industries. Such learning paradigm is generally lack of interactions between instructors and learners compared to conventional classroom training, the learning effect is questionable without proper design of the training program such as issues regarding courseware development, instruction mode, and training environment. However, many issues about how to design distance learning systems remain open. "Specifically, it must be determined what level of interaction is needed between trainees and instructors. Moreover, the nature of such interaction must be specified. For example, do instructors need to see trainees in order to conduct effective instruction? Do trainees need to see instructors or is it better for them to view other material? ... These and other questions must be addressed as a basis to develop sound distance-training systems." (Saias, 2001, p. 482)

In addition to e-learning, group learning, or, collaborative learning is one of the most frequently cited instructional modes and its importance has been widely acknowledged (Shebilske et al., 1998; Scanlon, 1995). Many studies have demonstrated that in many situations where learners work in groups, they outperform those who work alone (e.g., Lazarowitz et al., 1994). Cognitive theory tries to explain why group learning works. It emphasizes that the interaction among members increases the critical concept learning by itself (Damon, 1984). For cognitive-based problem solving tasks, cognitive elaboration states that the effect of group learning is due to the extensive elaboration of materials by group members to other group members. Since higher achievers have more opportunities to explain the system/task to lower achievers, they reinforce their knowledge and therefore learn more (Webb, 1989).

To evaluate the success of a training program, the skill acquisition rate is most frequently used performance measure. In addition, skill retention and skill transfer need to be measured and are traditionally investigated by manipulating feedback, practice intervals, reinforcement schedules, and other conditions during learning process (Schmidt and Bjork, 1992; Ghodsian et al., 1997). This study is to investigate how the nature of the interactions between trainees and instructor ("going-to" training or distance training) as well as training protocol (individual or group) affect learning efficacy and skill retention for a simulation-based training program.

Method

Simulation continues to be a popular method for delivery training and simulators are widely used in business, education, and the military (Jacobs and Dempsey 1993). A shop floor control simulation software was used for this research. This simulator was first developed by Goldratt (1996) to promote the Theory of Constraints (TOC), a production control theory that emphasizes bottleneck identification and buffer management in front of production bottlenecks. Figure 1 shows a screen printout of the simulator. The simulator is actually a small virtual manufacturing plant producing some products with certain manufacturing processes. The manufacturing routings are shown at the right side of the screen. In this case, there are 4 types of raw materials (RM) listed at the bottom of the screen that can be fabricated into three types of finished goods (FG) at the top of the screen. The number at the left of each RM and FG means the cost of the raw material and sale price of finished goods, respectively. On each manufacturing routing, colored rectangles represent manufacturing processes and black rectangles represent the buffer for work-in-process. The number on each process rectangle means the processing time.



Time: 0: 9 Pace: 1
Week: 1 Day: 1
Cash: 10000
Length in weeks: 1 Weekly expenses: 11000
ext. 310

Figure 1: Screen printout from the TOC simulator. (Avraham Y. Goldratt Institute©, 1996.)

The layout of the plant is shown at the left side of the screen and the colored rectangles represent the machines, corresponding to the manufacturing processes in matching colors at the right side of the screen. The number beside each machine represents the machine setup time. The capacity of each machine is fixed and the profit of selling each finished product to market is given. In order to increase net profit for a company, the goal is to identify and control the bottlenecks on the shop floor and reconcile conflicts among resources in order to maximize throughput within a fixed period of time. All the necessary information for running the production control tasks, such as the kinds of costs and demands, are shown on the screen and are updated as the simulation continues. The simulation ends after one week of simulation time. The performance measure for this production control task is the net profit measured in dollars.

Procedure

Sixty participants were randomly assigned into two training protocol, individual (IG) and triplet (TG), to proceed with the training. After a 30-minute introduction session to be familiar to the operation of the simulation software, a one-and-a-half hour of training session followed to finish three TOC problems. After the training session, a lecture was provided as feedback for learning TOC principles. The feedback was presented by an instructor using PowerPoint presentation. There were two types of interactions between trainees and instructor, one was "going-to" training (FTF) that was face-to-face with the instructor and the other was distance training (VDO) that a digitized video image was used to present the feedback lecture. Fifteen participants were randomly selected from IG and TG and were assigned to FTF. The rest of the participants were assigned to VDO. During the 30-minute feedback lecture, participants were video taped and their eye focus locations were categorized into three types, namely, focusing on the instructor, focusing on the PowerPoint slides, and other locations. After the lecture, training performance was evaluated immediately upon the completion of the training, after one week, and

BEST COPY AVAILABLE

after one month to observe skill retention. During the evaluation, each participant was tested individually regardless of training protocol and feedback presentation method. The test problem was different from training sessions but was based on the same TOC principles and used the same simulator.

Results

Table 1 shows the average performances for individuals (IG) and triplet groups (TG) over the three training sessions. During training sessions, higher achievers in a group usually led the discussion and operated the simulator. In other words, the scores obtained from group settings in training sessions were more affected by the higher achievers in that group. Therefore, it was not surprising to find that TG outperformed IG during the two training sessions ($p<0.001$) throughout three sessions.

Table 1: Mean performance measured during three training sessions and their standard deviations (in parenthesis) for different training protocols.

Training protocol	1st Session	2nd Session	3rd Session
IG	-2103(2350)	-75(2435)	2075(1854)
TG	402(1452)	1534(1087)	4024(943)

Table 2: During feedback lecture, the average time (min) that participants focus on different locations and their percentages (in parenthesis).

Feedback representation	Instructor	PowerPoint slide	Other
FTF	17(57)	9(30)	4(13)
VDO	7(23)	14(47)	9(30)

Table 3: Mean cubic root of net profit measured in dollars for the different levels of three main effects and their standard deviations (in parenthesis)

Factor	Level		
Skill Retention	Immediately	After one week	After one month
	13.53 (3.52)	13.46 (3.89)	10.55 (6.16)
Training Protocol	Triplet (TG)	Individual (IG)	
	13.79 (2.57)	11.23 (6.11)	
Feedback Representation	Face to face (FTF)	Video (VDO)	
	13.59 (3.78)	11.44 (5.53)	

The average time of participants' eye focus locations is shown on Table 2. Although the data were not subject to statistical analysis due to small sample size (4 samples for each feedback representation), it can be shown on Table 2 that the eye focus locations are quite different for the FTF and VDO cases, particular when contrast between time on instructor and time on PowerPoint slides. This result seems to suggest that different ways of presenting lecture divert trainees' attention to varied locations.

The focus of the analysis is the individual performance after training. In order to satisfy the "homogeneity of variance" assumption for analysis of variance, the performance measure, net profit measured in dollars, a data transformation using cubic root was performed. An ANOVA on the cubic

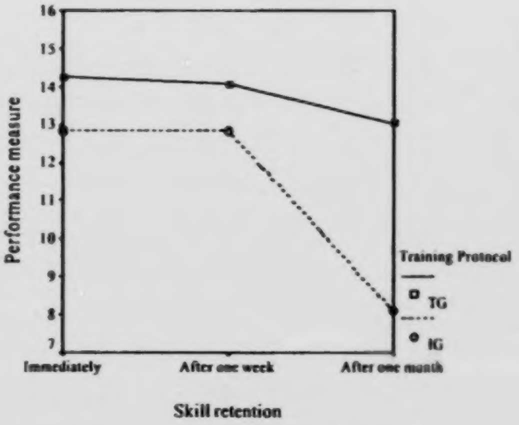


Figure 2. The mean performance for training protocol and skill retention

root of net profit measured in dollars revealed three significant main effects: training protocol, $F(1, 56)=9.55$, $p<0.01$; feedback representation, $F(1, 56)=6.77$, $p<0.05$; and skill retention, $F(2, 112)=13.27$, $p<0.001$. Table 3 presents the mean cubic root of net profit for the different levels of these three main effects and their standard deviations. It can be shown that FTF outperforms VDO case and TG group outperforms IG group, while testing immediately and after one week outperforms testing after one month as revealed by Tukey test ($p<0.05$). Among all the two-way and three-way interaction terms, only one two-way interaction term, training protocol and skill retention is significant as shown on Figure 2.

Conclusions

This paper investigates how training protocol and feedback representation affect skill acquisition and retention. The results suggest that collaborative training facilitates skill retention more than skill acquisition. In fact, the performance measured immediately upon the completion of the training is not significant ($F(1, 56)=2.63$, $p>0.1$). However, the difference increases after one week ($F(1, 56)=3.73$, $p>0.05$) and is significant after one month ($F(1, 56)=9.55$, $p<0.01$) that can be shown on Figure 2. It has been suggested that for using simulators as learning media, the verbal interactions among group members facilitate higher-order thinking (Sherwood, 1990), and therefore may reinforce learned skill. This may provide a reason why collaborative training has better performance in skill retention. Although the two way interaction term feedback representation and skill retention is not significant ($F(2,112)=0.51$, $p>0.6$), which means feedback representation has no effects on skill retention. Feedback representation, however, is significant in terms of overall performance. Considering the after-training lecture is only 30 minutes and the only difference is the way the lecture was presented, the effects can not be neglect. Video tape analysis also suggests that the e-learning approach that conveying lecture materials solely through digitized video and slides without any post processing, not only decreases participants' attention but also reduces the time of eye contact between instructor and trainees. This difference may explain why using video stream has worse performance than conventional classroom training. Overall, the results suggest the media selection and instruction representation need to be carefully designed for e-learning environment. Directly transplant the courseware used for conventional face-to-face environment may cause underachievement at training.

Using the Knowledge Modeling Approach to Assess Effectiveness of Electronic Learning

Stephen Gilbert Taylor
Biology Department
Champlain Regional College
St-Lambert, Quebec, Canada
steveta@alumni.concordia.ca

Abstract: In designing and implementing a learning experience, it is useful to establish a model of the intended outcomes. The knowledge modeling approach provides a method for developing such a model. Once a model is developed it can be subsequently revised and, then can serve as a basis for evaluating the relative effectiveness of the instructional program. This brief paper introduces the methodology of the knowledge modeling approach and provides an example of how the author has applied this approach to the development of an instructional system.

The computer can be a powerful tool when deployed effectively to promote learning. In the age of the internet, we have the opportunity to deliver quality instruction aimed at particular target audiences and individuals. It is important, therefore, that we build useful programs and to do this there is a need to assess their impacts on the learners to be sure that we are meeting our objectives. The knowledge modeling approach is a representation of the learning process that has been developed to assist in the design of computer aided instruction. Using this approach requires that the instructional designer move through an iterative process to build, assess, and remodel the instructional product. It was applied to the development and testing of a tutoring system that is presented here as an example of how the process was carried out.

The knowledge modeling approach is based on a constructivist view of learning and posits that students build, test, and revise mental models of a subject matter as they participate in a learning environment. This means that there are two tracks through such an environment. The student's track must provide an adequate opportunity for model building and model testing. At the end of this track we should be able to observe distinct and predictable changes in the student's behaviours that will allow us to infer that learning has occurred. The parallel track is that of the instructor or designer of instruction. This individual must develop the environment and provide suitable activities for the learner to accomplish the objectives. Suitable feedback must be provided along both tracks to stimulate revision and adaptation. The feedback can come about as a result of an assessment process and is considered to be formative assessment when it is promoting revision and change. At the end of the tracks, a summative assessment determines the overall accomplishment of the learning objectives and the relative value of the program.

A major aspect of the knowledge modeling approach is that its first requirement is to determine the general goals and specific objectives to be attained through the learning environment. Although there are several ways of determining these, the author has developed a procedure using sticky paper (Post-It Notes). The desired concepts and skills to be learned are listed by writing these on to the sticky papers and placing them on a larger sheet of paper or wall. These notes can be easily moved, and re-organized to generate a large map or model of the desired outcomes of the instructional package. While making this *sticky paper knowledge web*, it is also useful to define the standards of performance that will be required at the end of the instruction. From this model, the objectives and consequent specifications of the instructional package are set down in writing. The knowledge web, objectives, and specifications are then used to develop the learning environment and test it to provide the formative assessment necessary for the designer track.

Production of computer aided instruction must progress to a certain point before it can be assess by sample groups of users. In addition to assessing the relative value of the various subsections of the program, several other issues should be studied. One should determine how attitudes are affected. These include attitude to the subject matter of the program as well as attitudes towards computer aided instruction in general. It is also important to ask students to assess technical aspects of the software, such as the interface design, use of colour, fonts and type sizes, usefulness of graphics and the quality an opportunity for feedback about their progress as they use the program.

The Virtual Tutee program was developed by the author for the major purpose of putting the student user into the role of a tutor rather than being a tutee. This was based on the commonplace notion that "to teach is to learn". There is considerable evidence from the literature on peer tutoring that the tutor always gains in these situations. The subject matter for this learning package was photosynthesis, a relatively complex topic in introductory college biology. The author developed the models of the subject matter using sticky paper as described above. Tests of subject matter competence and standards of performance were compiled early in the design phase. As the materials were being produced, small groups of individuals were asked to test various components and to comment on the interface design. Finally, all the materials were pilot tested on a small group of student users before the final revision and the summative testing took place. This provided the feedback to the designer-producer that allowed improvements to be made.

The tutoring environment consists of a printed study guide, very similar to a chapter in a college textbook, and a computer program constructed using Hypercard, a Macintosh hypertext program. In this program, Jack, the virtual tutee asks questions of the student user. The student composes answers using a menu of items which must be built into a meaningful paragraph. Jack then replies by commenting, and or asking another question. The user can also ask Jack questions and is expected to reply to these. The conversation between the virtual tutee and the real student tutor proceeds through the various levels of the subject matter, from the simple to the more complex approaches to this topic.

In the summative evaluation of the software, fifty college students participated in the testing, and were randomly assigned to four groups as they entered the computer laboratory. Groups A and B used the virtual tutoring approach, while groups C and D used a text with study questions strategy. In this way one could comment on the effectiveness of the computer simulation of tutoring. Groups A and C took a pre-test of the subject matter in order to rule out the possibility of pre-test bias. All students were asked about their attitudes towards computer aided instruction and background study of biology.

The impact of the two formats on the cognitive domain was determined by conventional multiple choice tests of subject matter competence. Both the computer users and the readers attained a benefit from their study of the topics. In fact, there was no statistical difference between the four groups on the tests of subject matter competence. While the inventor of a novel teaching method would like to see a superior result over the more conventional strategy, the test results supported the premise that students learn through teaching and provide encouragement for the development of other environments based on this type of strategy. In an evaluation of attitudes towards computer aided instruction, there was actually a slight dampening of enthusiasm after the use of the program. This was probably the result of having to learn how to use the interface. Students, however, were generally positive in their assessment of the technical aspects and enjoyed their experience. We could not ask the readers the same questions. However, almost all of them were unhappy to have to use the conventional approach and would have preferred to use the computer program. A Turing test of the conversational software revealed that students were willing to consider that Jack was a real person conversing with them through the use of a computer. Students expressed positive sentiments towards the computer program and the accompanying materials. There were no bugs or computer crashes while the program was running.

Obviously, there are limitations to the effectiveness of any evaluation. The tests of competence may include questions which are either not valid or not useful in testing the possible outcomes. Attitude questionnaires can inadvertently bias the respondent to give a desired answer. The sample group of users may not be typical of a larger population for which the software has been designed. It is also possible that the Hawthorne effect will be the reason for the positive evaluation when a novel teaching method is introduced. There is still a lack of standards and procedures for determining such things as screen design, font and size, and use of colour although certain conventions are becoming established. However, these limitations should not impede the use of more evaluation and assessment of the instructional package.

Good instructional design includes developing the goals and objectives, building an effective environment for learning, testing and revising the environment as real users pass through it, and providing the evidence that the environment has been effective. Through the use of methods proposed by the knowledge modeling approach, it would seem that the designers and producers of instructional materials can improve and refine their products as well as demonstrate their relative value.

Standard Assessment Components For E-Learning Materials

Abstract: The paper describes a set of reusable software components appropriate for Web based tests design. All tests are developed as general-purpose components and are easily customized via XML files and/or XML data from a database. The tests are implemented as Java servlets, Java server pages (JSP) and Java applets. The communication between test components and Learning Management Systems follows AICC/CMI guidelines for Web-based CMI Systems. The proposed test components can be used to include assessment capability to any web-based learning material. They are appropriate for knowledge evaluation, for estimating achieved level of comprehension and problem-solving capabilities of the learners as well as for verifying their ability to apply obtained knowledge.

Introduction

Currently an increasing demand for web-based training on all levels, universities, continued education, training within organization and companies is observed. Supporting self-directed learning process needs appropriate mechanisms for evaluation learners' progress and learning achievements.

Tests are an important element of learning and remain an essential ingredient for gauging a learner's progress. Different test procedures for self-assessment and knowledge evaluation from a distance are recognized. The web provides an effective yet inexpensive way to test knowledge, skills, and attitudes. Most of today's available Web based educational courses are intended mainly to learning or include simple single choice tests without appropriate feed back to the learner. Well-designed tests should (Horton, 2000):

- Let learners estimate progress toward their goals
- Emphasize what is important and thereby motivate learners to focus on it
- Let learners apply what they have been learning-and thereby learn it more deeply
- Monitor success of parts of the course so that the instructor and designers can improve it.
- Certify that learners have mastered certain knowledge or skills to meet a legal or licensing requirement.

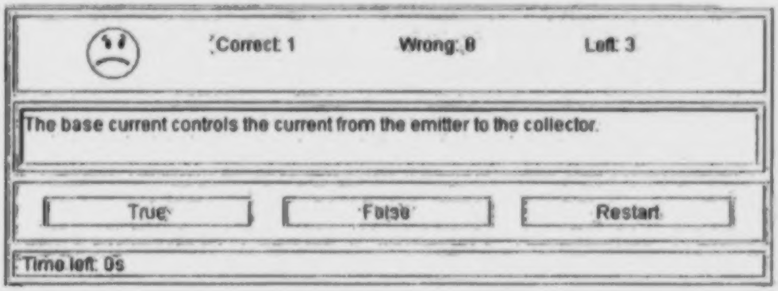
To answer market demands for knowledge testing in e-learning products and to facilitate tests design for different subjects our goal is to build generic software components that implement most widely used question types. The paper describes a set of reusable software components developed to fulfill requirements to Web based tests design. These components have to be easily customizable in order to be reused in test designs for different subjects. They should ensure adapting system to an organization's corporate identity as well as multilingual support. Another important requirement is their possibility to interface with Learning Management Systems (LMS) in order to keep assessment results in a centralized repository. For many kinds of tests, answers can be scored and result recorded automatically. Learning management needs statistics and reports, personalized curriculum and accesses, as well as multiple trainer and tutor support.

General-purpose Test Components

The most common used test types are the multiple-choice test, quiz, discovery test (discovery difference, discovery mistake), problem solving test, ordering test (sequencing or construction test), matching test, true or false test, fill in blank test etc. The paper describes functional specification and implementation of several test type questions. All tests types are developed as general-purpose components usable in different subjects, by different tutors and different language.

True/False Questions

True/false questions require learners to decide between two alternatives, typically saying whether a statement is true or false. This type of questions is organized as a time limited quiz. The idea is to emphasize what is important in learning material and thereby motivate learners to focus on it. Fig. 1 shows user interface of such test component. Scoring each question as the learners answer it provides immediate feedback, makes tests more fun and prevents misconceptions.



Correct: 1 Wrong: 0 Left: 3

The base current controls the current from the emitter to the collector.

Time left: 0s

Figure 1: True/False test with indicated incorrect answer

Multiple choice questions

Multiple-choice questions display a list of answers for learners to choose from. There are two main types of multiple-choice questions: *pick-one and pick-multiple*. The first type asks the learner to pick just one item from a list. The second type lets the learner answer by clicking one, some, all or none of the alternatives.

Fig. 2 shows a user interface of developed multiple-choice test. It allows more sophisticated questions than are possible with single-answer or true-false tests. They require making a series of related judgments. Scoring is performed after learners have answered all questions. Check facility marks correct and incorrect answers with different icons and delivers feedback to the students by summarizing results.

Multiple-choice questions are convenient for estimating learners' progress. They are easy to construct and easy to understand, but they do tempt some learners to guess rather than think.

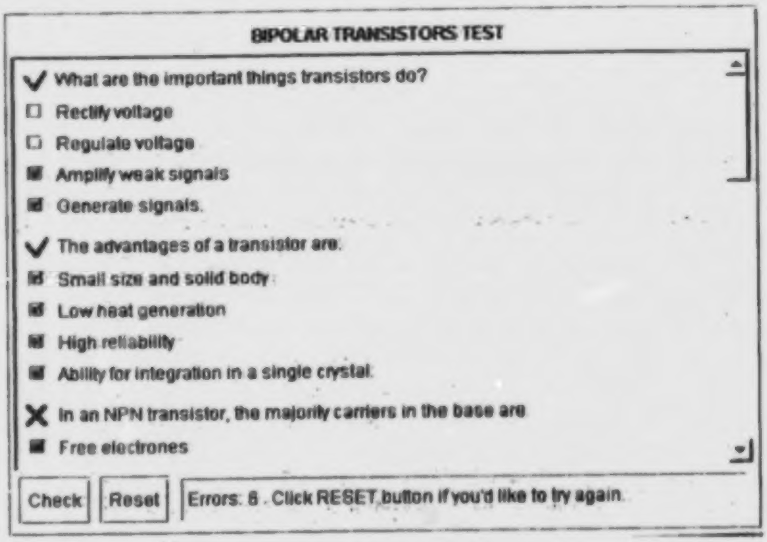
Drag and drop questions

Drag and drop questions require learners to move icons or images to specific location on the screen.

BEST COPY AVAILABLE

Drag and drop questions test the ability to assign the correct category or to arrange the parts of a system into a whole. They are used in several cases to test learner's ability to:

- Name things by dragging names into them
- Classify things by dragging them into boxes representing the categories
- Rank things by dragging them into position along a scale
- Assemble the pieces of a whole
- Show relationships among a family objects.



BIPOLAR TRANSISTORS TEST

✓ What are the important things transistors do?

☐ Rectify voltage

☐ Regulate voltage

☑ Amplify weak signals

☑ Generate signals.

✓ The advantages of a transistor are.

☑ Small size and solid body

☑ Low heat generation

☑ High reliability

☑ Ability for integration in a single crystal.

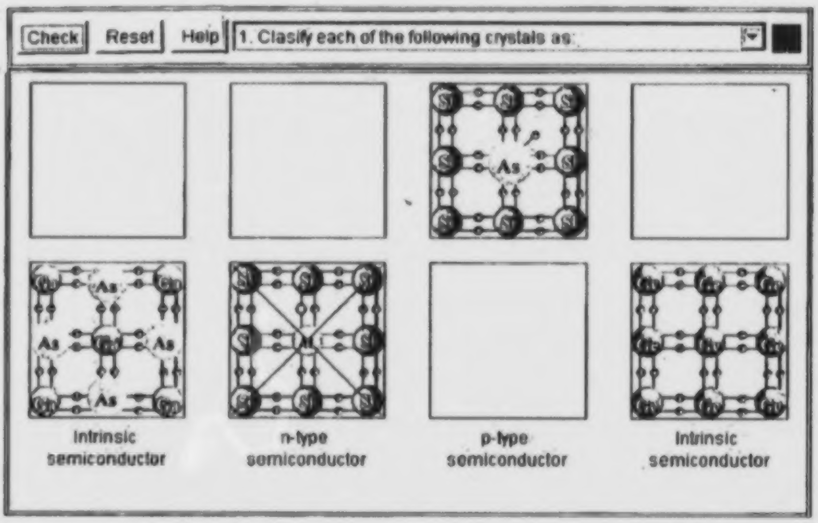
✗ In an NPN transistor, the majority carriers in the base are

☑ Free electrones

Errors: 8 . Click RESET button if you'd like to try again.

Check
Reset

Figure 2: Multiple-choice test with marked result



1. Clasify each of the following crystals as:

Check
Reset
Help
Si
As
Ge
Intrinsic semiconductor
n-type semiconductor
p-type semiconductor
Intrinsic semiconductor

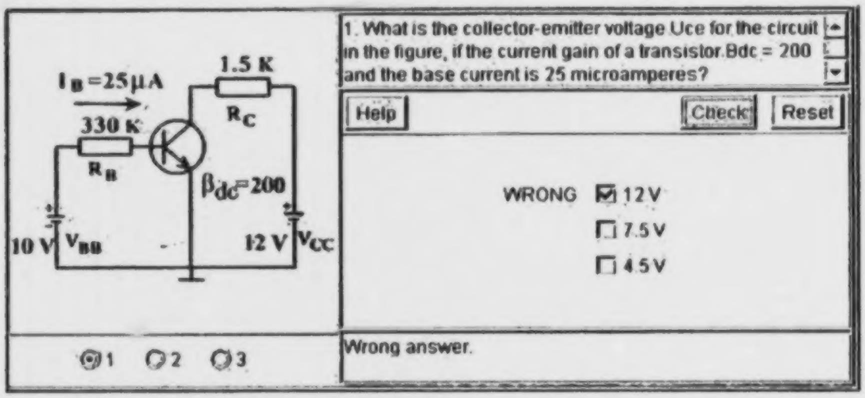
Figure 3: Matching image to text example

BEST COPY AVAILABLE

Fig. 3 shows an example of matching drag and drop test. It is used to test level of comprehension achieved by the learners and ask student to classify type of crystals non-considered before in the lesson.

Problem-solving questions

Problem -solving test (Fig. 4) verify learners' capabilities to apply obtained knowledge and check their ability to resolve problems not considered before.



1. What is the collector-emitter voltage Uce for the circuit in the figure, if the current gain of a transistor Bdc = 200 and the base current is 25 microamperes?

WRONG ☑ 12 V
☐ 7.5 V
☐ 4.5 V

Wrong answer.

Figure 4: Problem solving test

Tests Components Implementation and Customization

The test components are implemented as Java servlets, Java server pages (JSP) and Java applets. The communication between test components and LMS follows AICC/ CMI guidelines for Web-based CMI Systems.

All tests are developed as general-purpose components. To promote the widest possible adoption they are easily customized via XML files and/or XML data from a database. XML is a powerful, flexible, industry standard markup language used to encode data models for Internet-enabled and distributed applications. The XML structure conforms to LMS Question & Test Interoperability Specification. A custom java application named *Test Assembler* is developed to simplify the customization of test components.

Conclusion

The paper describes a set of reusable software components appropriate for Web based tests design. The functional specification of these components is outlined. The multiple-choice test, quiz, problem-solving test, construction test, matching test, true or false test are considered. The test components are implemented as Java servlets, Java server pages (JSP) and Java applets, which ensure platform independency. They are:

- General-purpose for using in different subject
- Platform independent and applicable to any hardware and software environment.
- Easy customizable for any subject and any language
- Compatible with Learning Management Systems (LMS) and support any language.

The proposed test components can be used to include assessment capability to any web-based learning material. They are appropriate for knowledge evaluation, for estimating achieved level of comprehension and problem-solving capabilities of the learners as well as for verifying their ability to apply obtained knowledge.

KEY STEPS FOR DEVELOPING E-LEARNING EVENTS – INTERACTIVE COURSEWARE DEVELOPMENT

Ms. Tenku Norishah Tenku Shariman
Head of Internet-based Degree Programmes Unit (IBDU)
Multimedia University, Malaysia
tengku.norishah@mmu.edu.my

Abstract: This paper will discuss and demonstrate (from initiation to completion and with real examples) the key steps, which are based on sound instructional design principles, for developing an interactive web-based e-learning courseware. The courseware that has been developed uses the web as the main interaction platform. Active learning is realized through cooperative and collaborative learning techniques which are integrated within the courseware. Support rendered includes the availability of rich learning resources, electronic workspaces and teacher presence (via on-line). The following sections will discuss the elements of the development process and how these elements have been translated into a web-based learning environment.

I. INTRODUCTION

Technology has revolutionized business; now it must revolutionize learning.
"We need to bring learning to people instead of bringing people to learning." (The Maisie Centre, Tech Learn 1999)

Powerful new technologies continue to create new possibilities for innovative delivery systems and creative learning outcomes. The broad definition of technology in education will probably continue to change and evolve in the foreseeable future. The application of new technologies to improve teaching and learning will necessarily follow ongping invention and development of new hard and soft technologies. For example, fast computers, the popularity and accessibility of the Internet, and the wide bandwidth of communication networks are together revolutionizing the traditional educational process. But merely allowing learners access to computers and networking them to the Internet, however, represent no 'real' advance. Improving students' learning in a digital environment requires the availability of powerful and insightful content. It is important to remember that the emphasis here is on LEARNERS, NOT on the TECHNOLOGY.

Successful e-learning may take place when learners are given the opportunity to experience free exploration of information as well as within strictly controlled environment. Educators should take into account the various learning styles before deciding to develop a learning activity. Instructional technology provides a vast array of media for us to choose from. Therefore it is important that a great emphasis on human needs and human characteristics is given.

II. INTERACTIVE E-LEARNING CONTENT

What does interactivity mean?
Interactivity means engaging and rewarding the learner during the e-learning event, not by leading them through page after page of theories only but giving them opportunities to explore, to practice (to fail even) and to emerge better equipped to tackle the tasks they face.

- Frequency of interaction
- Complexity of interaction
- Feedback Content and Quality
- Balancing Comprehension and Significance
- Learner Control

How can we produce interactive e-learning content or e-learning event?
Certain things we should always remember when we are designing e-learning event:
The learning events should

- emphasize on practical and meaningful learner involvement
  should connect solidly to instructional objectives
- encourage self-exploration
- take into account and respect existing knowledge
- focus on individual learners as fully human beings

- always emphasize on a democratic form of teaching because it would bring out strong individual effort in most learners.
- design activities that promote active learning

In essence, the e-learning event should be developed in such a way that learners are able to have a sense of focus and task orientation without feeling brutally forced to do work.

III. THE KEY STEPS (based on Instructional Design Principles)

The key steps are:

- Analysis of the setting and learner needs
- Design of a set of specifications for an effective, efficient, and relevant learning environment
- Development of all learner and management materials
- Evaluation of the results of development both formatively and summatively.

1. Analysis

- To analyze the problem areas that give rise to the learner's need for the learning event
- To analyze strategies which could make the learning experience more motivating and effective for the audience.
- To analyze how the various sections of the learning event will fit together:
  - Define learning objectives of learning event
  - List topics to be included in the learning event
  - List the pre- or co-requisites needed by the learners.
  - How many minutes/hours of study will be included in the event?
  - How is the event going to be delivered to the learner?

2. Design

- To design learning materials which are appropriate for the learner
- To design the structure for the content of the learning materials
- To design effective instructional strategies which include all three of the following components:
  - i. presentation to learners of new information related to the learning objectives
  - ii. activities by learners that require them to process the information and to provide a response
  - iii. assessment items which matched desired learning objectives
  - iv. feedback to learners to provide reinforcement for desirable responses and remediation for undesirable ones

  (Barritt, Lewis, Wieseler, 1999)
- Thiagarajan (1993) suggests three types of knowledge with specific instructional strategies:
  - Factual information
  - Conceptual
  - Procedural
- Content Design may the following e-learning activities:
  - simulation, case studies/problem solving, asynchronous discussion, debates and e-seminars or games with ample opportunity for online skills practice, testing and feedback.

3. Development

- Developing a navigation flowchart
  - The structure of a learning event -- a map showing the relationships between the pages/individual screens that together form the learning event
  - In order to navigate through a e-learning event successfully, learners need to answer the following questions:
    - i. Where am I?
    - ii. How did I get here?
    - iii. What can I do here?
    - iv. Where can I go?
    - v. How do I go there?
- Developing a storyboard
  - A storyboard is a pictorial and/or written synopsis of text, graphics, videos and animations, shown in the order they will appear in the finished presentation. A storyboard is one method which allows you to plan out in a simple fashion:

        i. How the major sections of the narrative look
        ii. In what succession they appear
        iii. The relationship between them
    - To create a strong, consistent visual design, where important elements are emphasized, and content is organized logically and predictably.
    - Components of a storyboard

- Developing the GUI (graphic user interface) and the various screen templates
    - The GUI identifies the learning event for the learners and provides them with an interface between themselves and the materials developed for the event.
- The graphics MUST:
    - Convey and illustrate the message/ content when the content is not explanatory enough
    - Enhance the message when the message is already clear in the text
    - Support the message when the message is already clear in the text
    - Allow interaction between the learners and the content.
- Screen templates help learners understand how the materials are structured because screen templates forms a mental map. Screen templates can include the following:
    - Topic menus
    - Introduction and topic summary screens
    - Materials discussion screens
    - Learner assessment screens
    - Event information screens
    - Materials presentation screens
    - Additional resource screens
    - Advanced organizer screen

4. Evaluation

- As part of the design and development process, you will have to complete a formative or ongoing review of the project to determine the appropriateness and overall effectiveness of learning materials
    - Using a formative evaluation procedure where learning materials are systematically examined to ensure they are meeting the goals and objectives set for the event as well as meeting the overall standards set out for the project.
    - Using a summative evaluation for material improvement prior to the material being delivered for the first time.

IV. OTHER IMPORTANT ISSUES

Learning Standards Compliant for Content Development

- To comply to International Learning Standards (for example: SCORM) content for e-learning should be designed as reusable learning objects.
- Definition of a learning object:
    - "Assignable units" for a learning management system
    - The smallest unit that a LMS assigns and tracks
    - A meaningful division of learning that is accomplished by a student in a continuous effort – that is one sitting (Jordan, Mann, Regalado, 2000)

Utilizing LCMS for delivery of e-learning content

The Virtual University Portal, which integrates Multimedia University's Learning Content Management System, provides a supportive web-based learning environment for students. The courseware developed fully utilizes this supportive environment to provide an active and interactive learning experience for learners.
Supported by the LCMS, the learning events within the courseware include cooperative and collaborative activities which "enable learners in a group to harness each others ability, skill and knowledge and thus, enabling learners to 'govern themselves' (Bruffee, 1998).

V. CONCLUSION

Whatever development environment, tools and technologies are used, sound instructional design will remain important. The combination of thoughtful planning with intelligent deployment of advanced authoring tools will result in myriad benefits for both content developers and learners. The most successful e-learning content should not only provide interactive e-learning events, but also relevant and meaningful context, which are able to grasp and retain the attention of learners as well as effectively guide learners to achieve the desired learning objectives.

THANK YOU

Note: Examples will be given for each key-step of the courseware development process and finally, the paper will end with a demo of a completely developed courseware.

Towards a total learning environment for the distanced adult learner

Sarah Teo Siew Chin
ICUS Pte Ltd
sarah@icus.net

Abstract: With the advent of the web-technology, learning at a distance takes a different form from the way many adults are used to in their earlier days in school. Considering how a distanced adult would have to learn and taking account of the traditional way in which he is familiar with, a holistic on-line learning environment is suggested in this paper. The learning environment includes the instructive environment, the situating and constructive environment, the supportive environment, the communicative environment, the collaborative environment, and the evaluative environment. Activities for learner participation are recommended for each environment.

The distanced adult learner

From the works of three researchers, C. Rogers, P. Cross and M. Knowles, we draw common principles for learning that are applicable to adults. Significant learning takes place when the subject matter is relevant to the personal interests of the learner. Adult learning programs should capitalize on the experience of participants. There is a need to explain why specific things are being taught. Adults need to be involved in the planning and evaluation of their instruction. Experience (including mistakes) provides the basis for learning activities. Adults are most interested in learning subjects that have immediate relevance to their job or personal life. Adult learning is problem-centered rather than content-oriented.

In addition to that, we also identify the requirements of an adult learner when he learns from a distance. The distanced adult trainee is isolated and he has many commitments besides work in the office. The element of motivation is thus a crucial issue. Major issues that face the distanced learner would be the lack of face-to-face communications with fellow classmates and teacher and the lack of immediate response that he gets when he was in a physical classroom. To ensure that learning is meaningful and focused, and that the learner "sticks to the course", he needs to become and stay responsible for themselves. The self-esteem of learner must be maintained and increased as he takes the on-line course. Opportunities are provided for the learners to interact with one another. Support is provided when needed in the course of their learning.

The total learning environment

The on-line environment should emulate the current traditional method that the learner is most familiar with. We consider the holistic environment that the adult learner has in a school / campus / home. We attempt to bring the various classroom/corner/library/study room into the total learning environment for the working adults, all at a distance, physically away from the teacher, from his classmates.

The total learning environment consists of sub-environments put together to ensure a meaningful and memorable learning experience. Learning does not happen from only one specific source. It happens through various means, from different persons. In a holistic learning environment, the following components are essential: the instructive environment, the situating and constructive environment, the supportive environment, the communicative environment, the collaborative environment, and the evaluative environment

The instructive environment

"Content is king" – it was said. The basic element in learning is the content, developed based on specific learning needs and objectives. This can be developed on print-based material, videotapes, workbook, posters and multi-media computer based training courseware, web-based on-line learning materials. These are domain knowledge and instructional strategies put together to ensure that learners learn. These instructions would answer to knowledge, comprehension and at most application level in Bloom's taxonomy.

Figure 1: The total learning environment

Content with achievable objectives, essential components of a lesson – including introduction, body content, conclusion and practice and self-evaluation. The attainment of objectives provides learning satisfaction, which acts as a motivation for moving on to the next segment of the lesson, adding up to the whole module. For the very busy working person, every short period of recess from their work can be used for the attainment of new knowledge. In addition, the learner should be able to pick up the information quickly and easily as and when it is needed.

Situating Environment

Learning content should not be treated as a self-sufficient substance that is separate and independent of the situations in which it is learned and used. The activity and context in which learning occurs is in fact an integral part of what is learnt, instead of being regarded as separable from or ancillary to learning. Essentially, there should not be a separation between 'knowing what' and 'knowing how'.

John Seely Brown, Allan Collins and Paul Duguid said that learning must involve activity, content and culture as they are interdependent. The model of situated cognition is based upon the notion that knowledge is contextually situated and is fundamentally influenced by the activity, context, and culture in which it is used. Learners need more than abstract concepts & self-contained examples - they need full-blooded, authentic activity. Authentic activities refer to the practices of the culture. The authentic activities include the breakdown from task to operations to actions that the learner needs to take for solving a problem. Such situating aids in initiating the learners into the working practices and culture of the real world as well as transferring the learnt knowledge to the authentic situations.

Transfer of knowledge from the instructive environment to the real-life environment is made concrete through situating the learner in their environment of their own culture, context and with authentic activities rather than merely providing the knowledge in the instructive environment. Learners should be required to perform tasks and solve problems in an environment that exposes them to the multiple uses to which they can apply their knowledge in future. Thus, the emphasis is on the use of conceptual, factual, procedural and principle knowledge to solve problems that are situated in the contexts of these knowledge. Learners will then develop a deeper understanding of the meanings of the knowledge, as they are able to develop memorable associations between knowledge and problem solving contexts.

By providing the learner a situation around an environment that he would encounter in his workplace, we provide the additional link to familiarity before he even meets the situation. This is preferred to a cold-start to the actual application of the learning.

The Constructive environment

The instructive environment that holds the content, remains the central part of the learning environment. It would start from the approach of posting the domain knowledge to the learner, in various

BEST COPY AVAILABLE

forms. As the learner picks up the knowledge, construct his own knowledge from it, he returns the newly constructed knowledge back to the system, adding up to the knowledge base. (CK Looi, 1998/9)

Learners should not be passive receptacles of knowledge. Papert (1990) distinguishes between constructionism and instructionism, arguing in favour of a constructivist model of learning where the learner will construct his own knowledge instead of relying on the teacher.

Collins and Ferguson (1993) proposed epistemic tools as the basic building blocks for knowledge construction to help learners to recognize, judge and organise patterns of information, engaging learners in constructive inquiry. Epistemic forms are "target structures" that guide inquiry.

In designing and developing simulated scenarios, there is requirement to provide various situations. As suggested by Situated Cognition supporters, situations should be varied and practice multiple, so as to prevent over-situating. As we develop the system for adults, we aim to capitalise on the vast experience of the adults. We allow them to share their experience, success and failure stories of projects, their encounters in war scenes, their experience in surviving in the jungle. These sharing are used as resources for designing of context-rich simulated scenarios and case studies.

The instructive environment, situating and constructive environment should be brought together in each lesson. This provides a proper seamless flow from learning new knowledge to practicing new knowledge and finally, to transferring new knowledge to the learner's own culture, context and activities.

Supportive Environment

There are two forms of support that the learner needs in the accomplishment of learning outcomes: performance support and cognitive support. Performance support comes in the form of tools for the performance of certain tasks that are required for the achieving of certain specific objectives, specific to the lesson or general to the course. Examples of these are cost-calculation tools, project scheduling tool that are required in a management course. Maps, coordinating instructions, compass, calculators, table of formulae are some performance support tools used in simulated military mission exercises.

Cognitive Support is provided by people who would be able to provide the coaching, molding, scaffolding and feedback to the learner, so that his knowledge is built up and eventually, he may reach an expert level to join in as an expert providing similar cognitive apprenticeship to others. We learn from many different groups of people. In this pedagogical framework, people where knowledge lays generally are identified: the learner himself, his peers, his instructor and the industry experts. Industry experts can be employed on a contract basis to provide the industry expertise, through published papers on related topics, newsletters, answering to specific queries, providing consultancy to specific projects, sharing of industry trends. Eventually, these questions and answers are kept in the FAQ (Frequently Asked Questions) section. And used as part of the content in the instructive environment.

Communicative environment

Learning on-line has the disadvantage of "hermit learning", i.e. learning on your own, in your own shell, without having to leave the home, without having to meet anyone. This goes against the human need of socialising, of having the sense of belonging. The communicative environment is essential to providing the learner with a sense of being with someone in the same pursuit. This need is even more acute for the not-so-independent learners, especially those who are used to learning with others. Communication must be encouraged in any distanced courses. The communicative environment is supported by the way the lesson is written and proper communication approach in face-to-face sessions. "Talking" tone should be used throughout the textual lesson to ensure learner of a personal, approachable teacher, not unlike that which he is familiar with in his earlier days in school.

The use of email, threaded discussion, echat, video conferencing, and audio-conferencing are some ways to encourage communication amongst the community of learners. However, while these tools may be amply provided, it requires the active participation of all involved. Feedback or replies need to be timely and constructive. Learners need to be assured of the receipt of assignment submitted to the instructor. Evaluation of the submitted assignment must be provided to the learners soonest so that learning of the following lessons will not be hampered. When learners are actively communicating and interacting with experts for the purpose of solving problems and performing tasks in a domain, a culture of expert practice that helps situate and support learning is created.

Collaborative environment

Working collaboratively allows one to view objects with varied perspective, providing a richer learning environment. Groups are not just a convenient way to accumulate the individual knowledge of their members. They give rise synergistically to insights and solutions that would not come about without them. This mode of problem solving is therefore an additional source of scaffolding for the learners as the knowledge is distributed throughout the group of learners.

Learners are given the situated opportunity to develop skills needed for collaborative work. With the collaborative nature of today's workplace, knowing how to learn and work collaboratively is increasingly important. Assignments and projects should be designed to promote collaboration among the learners. The social aspect in learning is catered for, as teamwork is required in completing the assignments or projects.

Evaluative Environment

Evaluation is concerned with judgements of worth. Different people who have legitimate interests in the evaluation data collected should be involved in evaluation. These stakeholders are the learners, peers of the learner, the instructor himself, the experts and those who manage and sponsor the course.

Evaluation focuses on two main aspects: learning effectiveness and training efficiency. Learning effectiveness is concerned with the assessment of worth within the training event. It addresses questions such as 'How much has been learned' or 'Have the methods selected worked well'. On the other hand, training efficiency assesses the value of training event in terms of operational indices (e.g. wastage rates, quality), financial indices (e.g. increased output from given resources) and personnel indices (e.g. work punctuality).

Different stakeholders employ different criteria of worth to evaluate the success of a program. For instance, sponsors of the training program would be more concerned with measuring the efficiency of training to determine if there is a reasonable rate of return on the resources expended on the training program. Adult learners would place emphasis on learning effectiveness to ensure that what is learnt will be of immediate relevance to their job or personal life. Self-evaluation should be provided for each module. This provides for the learner his progress in the course. Remedial action can be taken to ensure pre-requisites before the next level or chunk of knowledge is provided for him

Conclusion

On a distanced mode, it is critical that the adult learner is provided with a holistic environment in which knowledge is presented in an authentic context with the settings and applications that would be of immediate relevance to him. In this environment, learning is acquired through opportunities for reflection, active construction of knowledge as well as by means of social interaction and collaboration. Careful and deliberate consideration is required in planning and designing the learning events so that the various sub-environments are integrated and blended for a meaningful and memorable learning experience, leading to a synergistic impact on learning.

CD-ROM Enabled Web Sites

by
Dr. Thane Terrill
Teachers College, Columbia University

Conceptual Overview

This paper will examine how to incorporate CD-ROM media with a web server in such a way as to maximize the sophistication of content while minimizing bandwidth constraints. Distance learning courses are frequently forced to accommodate the lowest common denominator amongst students. The limiting factor is almost always bandwidth. Given that most distance learning courses have their materials prepared before the course starts, it makes sense to transfer the materials to the students on a CD-ROM before the course begins.

Internet Bandwidth Inequalities and Limitations

It is easy to take the frequent announcements of the Internet's triumph as proof of its ubiquity. Unfortunately, this is little more than preaching to the choir. Those not enjoying the benefits of the Internet are, by their absence, prevented from disagreeing. Examining maps of Internet connectivity like *An Atlas of Cyperspaces*,[1] one discovers that Internet access is completely unavailable in many parts of the world and unevenly distributed everywhere else. The unpleasant reality is that even a highly motivated student may find it impossible to obtain the connectivity required for an Internet-based course.

In a distance-learning course, where participation is mandatory, instructors are often forced to remove desirable features from their web sites so that none of their students can claim they are unable to participate in the course.

Even within North America, the average connection speed is approximately 35kb[2]. While this speed is sufficient for browsing web pages that are mostly textual, this speed is not enough for good quality video streaming or for opening documents with numerous graphics.

Integrating the CD-ROM

The method by which a web site can be "CD-ROM enabled" is actually fairly straightforward. The instructor places all the course materials on the web server. The same content is then placed on a CD-ROM, which is mailed to all students enrolled in the course. While a static web server can be used with a CD-ROM, the project works far better with a dynamically built web site that builds a new page whenever it is accessed.

The key is that the user logs into the server and in his or her preferences tells the server the location of the CD-ROM drive. So, for example, on a standard PC, the CD-ROM would most likely be in drive "D" or "E." When the web server builds a page or produces a search engine listing, it is able to draw the content from either the web server or from the CD-ROM. Naturally, loading content from the CD-ROM would be equivalent to loading from the fastest Internet connection.

While the author is unaware of anyone having developed a "CD-ROM enabled" web site like the one just described, the basic concept is actually quite common. Most of the largest Internet sites, like Yahoo! and CNN, dynamically adjust the location of the content so as to make for faster delivery. Usually, these large sites contract with content distributors, like Akamai (http://www.akamai.com) and Digital Island (http://www.digitalisland.net), to position content in multiple servers strategically located. When a visitor comes to a web site, the content distribution system sends all or part of the content from the server closest to the visitor. By finding the fastest path through the Internet, the user has the fastest possible download and the provider has off-loaded traffic to remote servers. Drawing content from a CD-ROM on the users own computer is just one more application of the principles of content distribution.

Technical Aspects

Naturally, any system that requires a high level of complexity can be seen as solving one problem at the cost of creating another problem. This project is fairly simple for anyone already familiar with creating a database-based web site.

The core of the system is the database. In a database-based system a record in the database, whether it be a Word document, an HTML page or a streaming video file, references every content object. To "CD-ROM enable" the site, the database must have an additional field indicating that the content object is on the CD-ROM. If there is more than one CD-

ROM or there are multiple editions, additional fields may be required. The database also needs to have an additional field in the user preference database. The most important new field is the one that designates the location of the user's CD-ROM drive. More fields may be required for more complex requirements.

The code that builds web pages and displays the results of on-line searches needs to be augmented so as to offer an auxiliary link when content is known to be on the user's CD-ROM. This activity may take two essential forms: 1. the web page may be automatically loaded from the CD-ROM and the user is not offered an option; and,2. the dynamically built web page may display links that are both on the server and on the CD-ROM.

In some situations, additional steps may be required. For instance, in a situation where a document has been updated but must retain the same filename and location, the system would have to be told to ignore the version on the CD-ROM. The simplest way to accomplish this by clearing the field that indicates the file is on the CD-ROM. However, with very large documents, it may make sense to allow the user to pick the file from the CD-ROM with some sort of indicator that there is a newer version. This would be a desirable option for someone in a poor bandwidth situation with a large document or video file when the differences between the CD-ROM version and the version on the web site are trivial.

Requirements for Successful CD-ROM Deployment

Not every Internet project can benefit from the use of CD-ROMs. The content to be delivered must be specific enough to be containable within the 700 mega-byte limit of a CD-ROM. Multiple CD-ROMs are possible, but may be unwieldy. DVD disks are natural successors to CD-ROM, but are not yet in wide enough use to be considered at this point. When DVDs become common, the use of high quality video becomes realistic.

While courses that have fairly static content are best served by having a CD-ROM, these CD-ROMs can be used in situations where new documents are being added or old documents are modified. New documents simply will not have an accompanying link for the CD-ROM. Modified documents will be marked in the web server's database as not being on the CD-ROM. Naturally, if the volume of new and modified documents are substantial, the instructor may consider sending out a second CD-ROM. In fact, the database can easily determine what to present on the web page based on which CD-ROM the student has in his or her possession.

Concluding Remarks

The integration of CD-ROM media with web servers gives the distance-learning instructor the freedom to design for the student's needs without consideration of bandwidth limitations. At some point in the future, the Internet will live up to its advertising and work-arounds, like the use of CD-ROMs to augment web servers, will be superfluous.

Extending Distance Learning Courses with CD-ROM Media

by

Dr. Thane Terrill

Teachers College, Columbia University

Submitted to E -Learn 2002
October 15, 2002

Conceptual Overview

This paper explores how CD-ROM technology can provide a very effective way to overcome some of the Internet's extensive bandwidth and connectivity problems for distributing large volumes of static multimedia information to globally distributed users, particularly those users outside the high-technology areas of the world. The concepts explored came out of an actual project undertaken by the author in his capacity as Network Administrator for a religious Non-governmental Organization.

The Internet is unquestionably the most exciting medium for the delivery of educational content today. One of the principle beneficiaries of the Internet's global reach is the distance-learning instructor. While distance learning has expanded rapidly due to the development of the Internet, there are factors built into the Internet as it now functions that clearly limit the richness and depth of what a distance-learning instructor can offer students.

Limitations of technical proficiency on the part of instructors and students can be overcome with training. Other limitations, however, are harder to circumvent. One of the most significant is the limitation in access and transmission speeds on connections outside regions like North America. Universities in these better-connected regions of the world frequently have much better connectivity to the Internet than do many of their distance-learning students in other regions of the world. One result of this disparity is that the instructor must either reduce the sophistication and amount of the material distributed via the Internet or accept the loss of some percentage of prospective students. Unfortunately, the students left behind are usually the very ones most bereft of educational alternatives and most in need of distance education.

This paper argues that CD-ROM technology, when used as a means for storing and sharing data, can ameliorate the current limitations on distance-learning courses resulting from poor Internet connectivity.

Frequently, CD-ROMs, as a content delivery medium, are viewed only as a competitor to the Internet. This view is perhaps based on the differences between both the content creation tools and the type of content normally associated with each medium. While CD-ROM production is normally the realm of professional content creators using complex tools, like Macromedia's Director[1], the Internet has developed as a medium for which almost anyone can create content. Over time, the public has confused the properties of the content normally associated with CD-ROMs with the properties of CD-ROMs as a delivery vehicle. It is the author's contention that, when CD-ROMs are used to deliver content made by tools used primarily for the Internet, the resulting hybrid has properties very advantageous to the distance-learning instructor.

CD-ROMs can be viewed in Internet terms as packaged bandwidth delivered at ultra-high speeds. Clearly, CD-ROMs cannot replace all the interactivity of an Internet-based course nor can the content be updated in real-time. On the other hand, most content in a distance-learning course remains static for the duration of the course.

When viewed in terms of the poor connections available in most countries of the world, CD-ROMs become an attractive method for transporting static information, particularly if it is voluminous. As a complimentary method of delivering content worldwide, the CD-ROM is more than a convenience in many parts of the world; it may be the only realistic means by which Internet-based courses can be made fully available.

This paper will survey the current limitations of the Internet as a content delivery vehicle and will suggest how CD-ROMs can be used to work around these limitations. The author will then briefly describe the hybrid CD-ROM/Internet project that inspired the model described in this paper.

Internet Bandwidth Inequalities and Limitations

It is easy to take the frequent announcements of the Internet's triumph as proof of its ubiquity. Unfortunately, this is little more than sermonizing to the converted. The far more numerous but silent groups not enjoying the benefits of the Internet are, by circumstances, prevented from disagreeing. Examining maps of Internet connectivity like *An Atlas of Cyberspaces*,[2] one discovers that Internet access is completely unavailable in many parts of the world and uneven in its distribution everywhere else. The unpleasant reality is that even a highly motivated student may find it impossible to obtain the connectivity required for an Internet-based course.

In addition to these physical constraints, students may have other obstacles imposed on them. For example, students connecting to the Internet from their places of work may find that company firewalls forbid certain types of connections. Even when there are no apparent obstacles, Internet connections can prove fragile. On November 20, 2000, Australia lost a major sea cable to sharks,[3] and on February 9, 2000, China lost a major connection to the Internet to a fishing trawler.[4] In both cases, repairs took weeks. One need not look to the oceans to find significant outages. In August of 1999, MCI cut off a large segment of Chicago's largest firms in what MCI called a "meltdown of the network."[5]

Determining the Internet Value of CD-ROM Distribution

Internet usage in North America and Western Europe is well above that of other parts of the world. While Internet providers are creating new services to take advantage of the increasing number of high-bandwidth users in the Northern hemisphere, the needs of other markets are ignored. Reports from overseas suggest that, even when Internet access is available and dependable, users often limit their time to a few hours a month because of cost considerations.

When one looks at CD-ROMs as stored Internet bandwidth, it is logical to consider the cost of that bandwidth in terms of Internet transmission fees. In Zimbabwe, for example, a user with 14k baud modem would require approximately $170 USD to retrieve the 650 megabytes of information stored on a CD-ROM. A 56k baud user in Finland would pay approximately $25 USD. CD-ROMs typically cost from $0.50 to $1.50 USD each to produce.

Significant Advantages of the Distributing Static Content via CD-ROM

Using the common Internet formats (i.e. HTML, PDF[6], Real Audio, etc.), instead of the standard tools used to develop CD-ROM-based content, CD-ROMs become both easier to develop and easier to use. Not only does using common Internet formats benefit the content developer, it also reduces training time for the user, because he or she may already be familiar with Internet browsers. The learning curve is reduced further when the content creator follows commonly used Internet user interfaces. Traditional CD-ROMs frequently have non-standard user interfaces that make them hard to learn. While the Internet also has user interface issues, the use of a standard browser provides a basic level of consistency. Support concerns are lessened by the fact that the programs used are being used by millions of other users.

Additionally, the use of programs like Real Audio Player[7] or Apple's QuickTime player[8] make it possible to distribute video content without concern for conflicting video transmission standards (i.e. NTSC, SECAM, PAL) found with VHS video tapes. While streaming video over the Internet also circumvents this constraint, bandwidth demands for streaming video are often prohibitive. A nice side benefit of distributing content via CD-ROM is that the content creator does not need an expensive stream server, since the video is running from the CD-ROM. Moreover, in the author's experience, the quality of a video played from a CD-ROM is almost always better than the quality offered by an Internet connection.

Using a CD-ROM does not preclude the complimentary use of the Internet; it merely provides an alternate vehicle for the transmission of static content. Valuable Internet features not found in CD-ROM technology, like e-mail and discussion groups, can be allocated at available bandwidths.

To use a CD-ROM, the student need not own a computer, though access to a computer is essential. Fortunately, access to computers can often be found at schools, libraries, work places, Internet Cafes, and the homes of friends. One of the advantages of using an Internet-based CD-ROM is that it can be used without installing any new programs on the host computer. This is an important attribute, given that public computers are often set up to forbid the installation of software.

As long as the computer has an Internet browser, data can be read directly from a CD-ROM, as if it were a web site. Since the computer does not have to be connected to the Internet while a CD-ROM is being used, the user does not need to worry about accumulating charges or taking a telephone line out of service.

Concluding Remarks

The fragile and expensive international Internet connections that make CD-ROMs interesting as substitute bandwidth will probably continue well into the future. With the advent and broad distribution of reasonably priced DVD technology, the reasons for using "stored bandwidth" will be even stronger. In fact, DVD technology will allow for the inclusion of high quality video and other resources that go beyond the capabilities of the current Internet.

The University of London eUniversity Project: Collaboration and Cultural Change in a Complex Institution

Cate Thomas
Virtual Campus Project Manager
Teaching and Learning Technologies Team
University of London External Programme
United Kingdom
cate.thomas@lon.ac.uk

Abstract: The University of London External Programme is developing an e-university to enhance its international distance learning programme, which currently has 30,000 students. London is a collegiate university and so this requires collaborative development between stakeholders in the Colleges and in the departments of the central University, all of which have their own distinct identity and culture. The aim is to create a virtual university of which all partners have ownership and in which all participate in designing, building, maintaining and further developing. The challenge of bringing this about, working with academics, technologists and administrators to bridge cultural, institutional and occupational divides has meant forging new ways of working. Change is being managed using a 'from the ground up' cross institutional approach and using existing technologies innovatively, to build the community essential to successfully grounding our project in the organisational culture.

Introduction

The University of London's External Programme has been providing distance learning opportunities for over 150 years. It currently has 30,000 students in more than 180 countries worldwide engaged in over 80 programmes of study. To enhance provis ion to students it is now developing eUniversity functionality. London is a Federal University, so the eUniversity provision is being developed as a collaborative project between the eighteen diverse Colleges and Institutes of London, and the central University. The project is led by the External Programme Teaching and Learning Technologies Team.

This paper will outline what this eUniversity project seeks to achieve and discuss the challenges and opportunities involved in implementing this within a large, complex institution.

What is the eUniversity for London?

There are three phases to this project. Phase one was completed in spring 2002 and involved building a portal website (http://www.londonexternal.ac.uk/.) The site provides potential students with a wealth of in-depth information and pre-course guidance about study opportunities. They can, for example, download prospectuses, get detailed advice about eligibility, access study resources about distance learning, find out about the specific College offering their programme and 'meet' ex-students. Current students on the first three e-learning pilot programmes can use the portal to: access resources specific to their studies through the online library; contact other students using the student-to-student mail network; download previous sessions' exam questions; work through online tutorials; and access up-to-the-minute news about their programme of study. All of this enables the University to provide a faster, improved and more comprehensive delivery of service to students and potential students. With around 70,000 hits on the site per day, the take-up rate for this first stage is encouraging.

Phase two involves the delivery of a Virtual Learning Environment (VLE) using Lotus Domino technology, which will provide fully functional online courses for students. Importantly, it contains a function to keep telecommunication costs down for the student, in that by hitting the 'offline' button the student can access all the tutorials, seminars and other materials and activities available without being connected to the internet for long periods of time. They can then hook back up when they wish to post a message. The London VLE offers a flexible, adaptable environment which course leaders can use to construct a wide range of differing learning experiences. It has been piloted with two courses and will go live with Finance and Management courses in August 2002. Other programmes will be introduced throughout 2003.

Phase three will involve students being able carry out a range of activities, such as application for courses and payment of fees, online. This will vastly improve the turnaround time for students' interaction with the University - a factor which is vitally important for a distance learner.

Developing Virtual Community

The Colleges and Institutes of the University are spread throughout London and the surrounding area, and each has its own distinct culture and identity. For those at the centre co-ordinating this development the challenge is to create a network where academics, learning technologists and administrators from all the Colleges can work collaboratively to create a shared, distance-learning, eUniversity which all can own and participate in. A 'from the ground up' approach is being taken by creating an interdepartmental, and intercollegiate network of early adopters. A significant challenge has been to find mechanisms to facilitate this network, given that those involved are geographically dispersed throughout a large city, are varied in their occupations and institutional approaches to network building, have differing levels of experience of e-learning and need to manage their involvement in this project on top of their already demanding workloads. A range of communication solutions has been trialed for implementing this, which have had varying degrees of success. So far we have found: that networks are more likely to work if they are initiated with a face to face meeting; that solutions which rely on participants initiating action such visiting a particular webpage regularly tend not to encourage active participation, even if the participants are prompted; that specific, highly focussed networks, linked to carefully selected resources have been far more successful than more generalised fora; and that solutions which push information to participants are more likely to result in active involvement.

Collaborating on technical solutions - the challenge of a shared VLE

Each College has its own distinct organisational culture, each provides a very different range of subjects, and approaches to teaching and learning vary right across the spectrum. How then could it be possible for the centre to provide an Institutional VLE that would not only meet such a diverse set of needs, but would also be sufficiently flexible to cope with unforeseeable future developments and, additionally, would meet the needs of our International student market?

A range of market leading 'off-the-peg' VLEs were trialed with early adopters in a number of Colleges. The conclusion was reached was that, although this was not necessarily explicit, each VLE has, to some extent, a built in pedagogical approach, which might be suitable for some courses but not for others. Additionally, investing in a VLE would mean being tied to that particular product because exporting content between VLEs was generally not a trivial task. From a business viewpoint this was not ideal, as any given software product does not have an assured future - it may be decommissioned or it may become marginal within the market. In order to futureproof development another kind of choice had to be made.

An additional important deciding factor was the need to provide an affordable service for students. The University of London External Programme 30,000 student body is International and there is no control over the speed of data transfer or cost of connectivity students might have when using the online materials. It was important that students should be able to take the Learning Environment offline and still have access to all the materials available in the online Environment. None of the standard VLEs available at the point when the platform was chosen were able to offer this.

The solution adopted was to use the existing functionality of Lotus Domino to create a wide range of different VLE tools. Course leaders can then choose from these and have them customised to meet the needs of their individual courses. This means that academics can participate in creating a Learning Environment where they can choose the teaching and learning approach that best fits their discipline. Additionally, the look and feel can be altered to meet Colleges' individual 'corporate' identities. Domino outputs HTML, so should the decision be made to change to another platform some years down the line, or should there be a need to work with more than one platform, the fact that the content is held in this reasonably 'neutral' format would be advantageous. Finally, in terms of offline access, an Environment build using Domino has the advantage of the domino offline services (DOLS) function which enables the full offline replication necessary for use by geographically dispersed distance learners.

Cultural Transformation

As an organisation, the External Programme of the University has long established and successful ways of working. The eUniversity development means that we will need to further develop the way we work in order to accommodate an electronic dimension, whilst at the same time continuing to run our existing business. This will be a complex process, requiring a sophisticated range of change management activities to be collaboratively developed to suit our needs. It is envisaged that the eUniversity functions will become embedded the way that the University's distance learning provision works. Rather than being a separate and distinct activity, as some commentators have anticipated the so called 'e-learning revolution' as being, they will merge with and complement more traditional modes of provision, enabling London to develop its 'e-university' in an evolutionary manner. One example of this is the organisation-wide Web User Group. This is facilitated by the Teaching and Learning Technologies Team and comprises delegates from all nine administrative departments. It's aim is to agree policy and strategy for the portal website, working hand in hand with operational aspects of all departments and integrating the availability of web based information with print based. Most participants are new to web development, but are very knowledgeable about their own specific area. What has evolved is a dynamic and creative group, which not only assists the appropriate development of the portal site, but also reflects back on other activities and processes of the organisation from the perspective of web site development. Thus adjustments are made, and the focus of the organisations work practice shifted by informed, collaborative discussion and activity.

Conclusion

The lessons that have been learned from this activity across London form our evolving model for a collaborative approach to supporting HE providers' virtual community building for e-learning. We believe that this essentially practical and workable model which is effective even in a such a large, diverse and traditional organisation, offers the wider HE community a window into an effective, time and task efficient method of building collaborative community across the divides of occupation, experience, culture and institution.

Smart E-Classrooms, Traditional Classrooms and Critical Thinking

Abstract

This paper presents the results of a study conducted to examine the impact on critical thinking of a traditional classroom versus a "smart e-classroom". Preliminary results compiled from data collected via the California Critical Thinking Skills Test instrument (Facione, 1998) indicate a moderate increase over a fourteen-week semester for graduate students. In addition, student perception results indicate that those in the smart e-classroom perceived more support for problem solving, critical thinking, and creative idea generation in the execution of their course activities, and by the textbook, than those in the traditional classroom. Strangely, they perceived conducting research to be better supported in the traditional classroom than in the smart e-classroom. There was no difference in the grades achieved. Student satisfaction surveys indicate students sustained or increased in satisfaction with the technology and its use in the classroom.

Introduction

The "smart e-classroom" is a classroom equipped with an array of high-end technologies designed to assist in the teaching and learning process. In our context, the smart e-classroom is defined as "an interactive multimedia electronic classroom networked to the Internet and housing a video/ audio/ keyboard/ mouse broadcast-on-demand system". (Coppola & B. Thomas, 2000) This system permits computers to be used individually or in teams. In team-mode, students can take control of each other's screens and keyboards and iteratively augment each other's work. Screens can also be projected to one or more stations and instructors can scan and intervene in the activities taking place on the various stations. These classrooms have the promise of contributing substantially to the education of students. (Branzburg, 2001; McDermott, 1998; Shneiderman, et.al., 1998; Soules & Adams, 1998). As such, we were interested in whether these classrooms have an impact on important learning skills, such as critical thinking (Facione, et.al., 1998). To this end, we conducted a study to compare the traditional classroom with the smart e-classroom, the results of which are presented here.

The Study

There were two sections of the same graduate introductory information systems course taught by one of the authors. One section was taught in a traditional classroom, with moveable chairs and the other in the smart e-classroom. The course was designed with a view to developing various aspects of critical thinking, including problem solving, conducting research, and creative idea generation, within a team-based approach. Course activities involved students working in teams at each class meeting, analyzing various aspects of a case, called Healthlite (Laudon & Laudon, 1999). At the end of the course, they analyzed a major case from the same textbook, called Ginormous, also in teams. Grades for these activities were recorded and analyzed along with the data collected via the California Critical Thinking Skills Test instrument (CCTST). Students' perceptions of the support offered to the acquisition of the critical thinking, problem-solving, conducting research, and creative idea generation were also collected, as was their perceptions of various aspects of technology's usefulness.

Results

Demographics:

There were 32 students in the traditional classroom section (TC), and 21 in the electronic classroom (EC). Most students were in the 20-29 age category (68% and 66%, respectively) and had moderate computer experience (50% and 67%, respectively). (See Table 1, below).

Table 1: Demographics

%		Gender		Age				Computer Experience		
	N	Male	Female	<20	20-29	30-39	39+	Min	Mod	Ext
TC	32	69	31	3	68	29	0	12	50	38
EC	21	52	48	0	66	29	5	9	67	24

CCTST Scores:

There were four fewer students taking the post-test than there were taking the pre-test in the traditional classroom and two few from pre- to post-test in the electronic classroom. There was relatively little change in the California Critical Thinking Test mean and mode scores for those in the traditional classroom from pre- to post-test. The mean went from 12.8 to 13.4 and the mode from 13 to 13.5. In the electronic classroom, however, the change was larger, from a mean of 11 to 14.5 and a mode of 10 to 14.5. In the traditional classroom, the median was higher on the post-test, 15, compared with 11 on the pre-test. It was about the same in the electronic classroom, nine on the pre-test and 8 on the post-test. (See Table 2, below).

Table 2: CCTST Scores

	Traditional Classroom		Electronic Classroom	
	PRE	POST	PRE	POST
N	30	26	22	20
Mean	12.8	13.4	11	14.5
Mode	13	13.5	10	14.5
Median	11	15	9	8
Std. Dev.	3.6	4.6	3.5	5.5

Performance:

There was no difference in performance on either of the cases. For the Healthlite case, the average grade was 78% in the traditional classroom and 80% in the electronic classroom. The average grade of the students in both classrooms, on the Ginormous case, was 78%. (See Table 3, below).

Table 3: Performance

%	Traditional Classroom	Electronic Classroom
Healthlite	78	80
Ginormous	78	78

Perceptions: Critical Thinking Skills Acquisition

Those in the traditional classroom perceived more support for conducting research (53%), than those in the electronic classroom (43%), in performing course activities related to the Healthlite and Ginormous cases.

(See Table 4, below). This result is strange as the electronic classroom permits access out to the Internet for research purposes. The electronic classroom was perceived to provide more support of problem solving, critical thinking and creative idea generation (Healthlite – 57%, 71%, 57%, respectively; Ginormous – 67%, 76%, 62%, respectively) than the traditional classroom (Healthlite – 53%, 66%, 53%, respectively; Ginormous – 56%, 59%, 50%, respectively), which is more in keeping with what was expected.

Table 4: Critical Thinking Skills Perceptions

	Traditional Classroom	Electronic Classroom
Healthlite		
-Conducting Research	53	43
-Problem Solving	53	57
-Critical Thinking	66	71
-Creative Ideas	53	57
Ginormous		
-Conducting Research	25	19
-Problem Solving	56	67
-Critical Thinking	59	76
-Creative Ideas	50	62

Conclusion

The results indicate a need for a more extensive study. While the CCTST scores showed a greater improvement from pre-to post-test for those in the electronic classroom compared to the traditional classroom, the performance scores showed no differences. In addition, the perceptions of the students did not match expectations with respect to conducting research wherein traditional classroom students perceived greater support than electronic classroom students, notwithstanding their ready access to Internet resources. The electronic classroom students did perceive better support of problem-solving, critical thinking, and creative idea generation than the traditional classroom students as was expected. Additional faculty teaching two sections of a course both in the traditional setting and in an e-classroom is important to understand relationship between final grades, the CCTST scores, and their own perception. The students' perception of the event did not match the action the faculty was able to witness in the classroom. Since the students register for a section of a course the selection to the e-classroom is random. We are not able at this time to see if a student changes sections based on their learning needs, (visual, auditory) to fit the environment. A more rigorous instrument needs to be developed which would address the pre- and post-student perceptions of the impact of the various technologies.

Abstract: This brief report is part of an on-going research study that examines the use of web-based software and services in pre-service teacher education classes. Through the study, the researchers investigated questions related to improving teacher candidate and faculty use of web-based resources as well as teacher candidate and faculty perceptions regarding benefits of using web-based software. Quantitative data was collected and analyzed regarding teacher candidate perceptions of the use of technology. Qualitative data was generated regarding student and faculty perception of benefits for using a web-based software product, in this case LiveText (www.college.livetext.com).

Background and Rationale

Web-based software has the potential to positively impact the professional development of teacher candidates and practicing teachers by increasing professional interaction, collaboration, and enhancing the utilization of time. One such software, LiveText (www.college.livetext.com), is a potentially powerful resource for use in classroom teaching, electronic portfolio development, and ongoing professional development for teachers following graduation. At the initiation of the study, the researchers were all faculty at a mid-western university considering the use of LiveText software for student electronic portfolio requirements. The rationale for undertaking this research was to investigate teacher candidates' attitudes toward technology and to attempt to determine how effective the use of LiveText software would be in teacher education courses, particularly as a platform for the creation of student portfolios. The original intent of the study was to also investigate the impact of web-based software on improving the complexity of teacher candidate interactions and collaboration in teacher education courses. However, as the study evolved the data collected did not support this latter examination.

Research Questions

The research questions examined in this report are as follows:

1. What are teacher candidates' self-perceptions of their abilities to use web-based and common computer technology?
2. What are the teacher candidate and faculty perceptions of the benefits of using web-based software in teacher education programs?

Method

Subjects

The subjects in this study were approximately 36 undergraduate students in pre-service teacher education courses at a regional university in the mid-west. Approximately half of the students were drawn from one section of a course entitled "Models of Teaching," taught by one of the researchers. The Models of Teaching course is one of the entry level courses in the university's teacher education program. The remaining subject population was drawn from a section of a course entitled "Teaching Reading in the Content Fields," taught by another one of the researchers. Teaching Reading in the Content Fields is a mid-level course in the university's teacher education program. It should be noted that originally a control group was also established to pursue control group comparisons, but the data from this group was deemed incomplete by the researchers due to the relatively low final number of participants (approximately eight) and the relative lack of significant intervention or treatment with the other 36 participants in the "Treatment Group."

Treatment and Procedures

All students willing to participate in the study, near the beginning of the study, were asked to complete a survey designed to measure student attitudes toward using technology (Hofmeister, 2001). The students (called the "Treatment Group") who used the web-based software in the study received a free subscription for the use of LiveText software. The use of this software was integrated through small sections of the courses to complete portions of the course activities. The students received little training in the use of the software, but instead were given directions for logging on to the web-based platform and were asked to investigate its capacity on their own as they completed various course activities. Near the end of the study, the participants were once again asked to complete the technology attitudes survey as a posttest measure. These students were also asked for brief written feedback regarding their perception of the value of using LiveText software in the course. Data regarding faculty perceptions of the efficacy of web-based software was also generated from the researchers in this study.

Variables and Instrumentation

There are three general variables in this study evaluated with qualitative and quantitative assessment approaches and instruments. Table 1 delineates the variables and the assessment/instrumentation used for each.

Table 1: Variables and Instrumentation

Variable	Assessment/Instrumentation
1. Attitudes toward technology	*Discussion Board Basic Skills Profile* (Hofmeister, 2001)
2. Student perceptions of LiveText	Simple writing prompt
3. Faculty perceptions of LiveText	Simple writing prompt

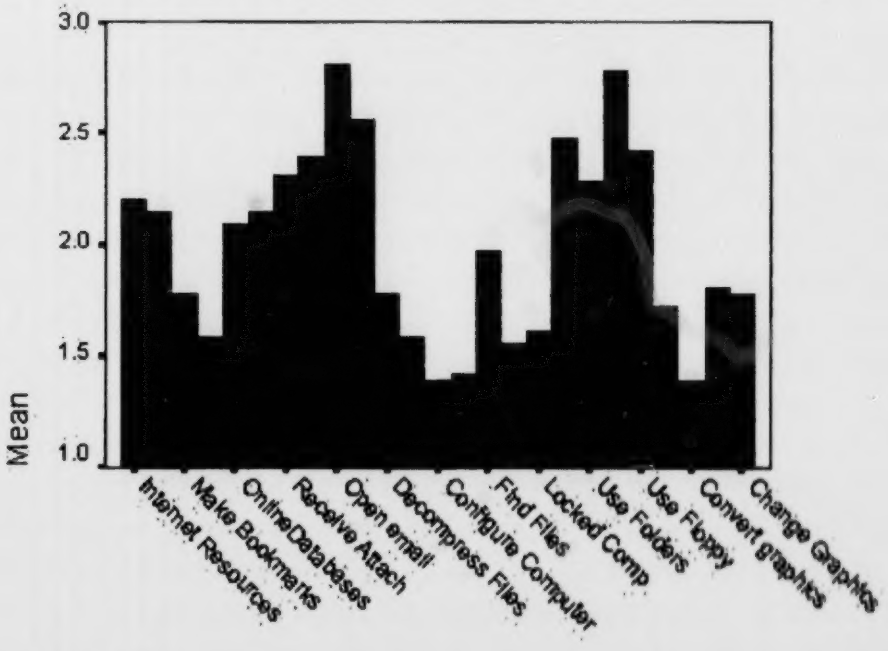
Research Design

This study was an evaluation study (Krathwohl, 1993) to provide the researchers with knowledge regarding pre-service teachers' attitudes and comfort with technological applications. The results of the study will guide future development of learning environments for pre-service teachers.

Results

The results of the attitudes toward technology survey, *Discussion Board Basic Skills Profile* (Hofmeister, 2001), are presented in Figure 1. This data represents the mean of all the scores (a mixture of pre and post-tests) entered by participants in the "Treatment Group" who used the LiveText software, along with the scores of one of the faculty researchers who also completed the survey. A review of these scores indicates that in general the pre-service teachers in this study are quite comfortable with and have positive attitudes toward applications related to email, the use of floppy disks, and the organization of saved documents through the use of folders. The scores indicate that the use of Internet resources, on-line data bases, and the organization of on-line resources through bookmarks represent areas in which the pre-service teachers in this study were less confident. The scores further indicate that pre-service teachers in this study have little confidence in their abilities to configure computers, decompress files, and utilize graphic applications.

Figure 1: Treatment Group Mean Scores



N=36

Qualitative analysis of the writing prompt to discuss perceptions of the use of web-based software led to the emergence of two major themes. Nearly all pre-service teacher participants expressed the view that web-based software such as LiveText has high potential to simplify the process of creating materials to support teaching, such as lesson plans and the creation of evaluative portfolios, as well as to ease he alignment of educational standards with education materials. The second theme that emerged was viewed as a disadvantage to the pre-service teachers. A majority of the participants seemed to feel that their lack of familiarity with the software left them at a disadvantage for utilizing the software to its full potential. The faculty researchers came to similar conclusions based on informal observations and discussions with the pre-service teachers as the web-based software was used in the two courses; to more fully utilize the potential of the web-based software, additional training and support would be needed.

Discussion

The results of this evaluation study can help provide teacher educators with knowledge of potential areas of strength and weakness related to pre-service teachers' abilities to utilize technological applications. Although the results can not confidently be generalized to a broader population, the study does identify areas in which pre-service teachers may have classroom-technology-related weaknesses and strengths. The ability to utilize applications related to word processing and e-mail seem to be well with in the established skill set of a majority of pre-service teachers. However, the results also indicate that, particularly without further training and support, full utilization of web-based software and Internet resources for educational purposes is not part of a majority of pre-service teachers' repertoire of technical skill. These results lead to the researchers to the conclusion that additional time in teacher education courses should be devoted to using web-based software and resources to increase pre-service teacher confidence and ability to utilize more aspects of web-based tools, particularly of cutting-edge applications such as LiveText; without proper support and training, these powerful technology tools may be unable to serve their designed purposes. Further research in this area is warranted to determine the impact of time, instruction, and variety of use on pre-service teachers abilities to use web-based software and resources with confidence.

Introducing Blended Learning to the South West of England

Dafydd Thorne – Exeter College, England

Exeter College is situated in the South West of England. In this region, a sparse and widely separated population along with poor communication systems make for a prime market for e learning.

One section of that market is made up of management staff in the 'Voluntary Sector'. That is to say people in management roles in the wide range of organisations in the 'not for profit' sector; charities, old peoples' homes, hospices, animal sanctuaries, cultural agencies, support groups etc. Typically, many of these organisations are small, independent bodies with very few full time employees most of whom are performing management roles in respect of teams of volunteer or very low paid part time staff. Such managers are often well educated in their own right but, almost invariably, in discipline a long way from the demands of their current roles. Even those with Business or even Management qualifications acquired their degrees or diplomas in contexts far removed from their current employment. Learning geared to the demands of specialist roles in national or even international corporations is scarcely apposite in organisations where there is often only one full time member of staff whose responsibilities encompass the full range from accounting and financial control via marketing and advertising right through to human resources and employment legislation. Acquiring and maintaining a consistent funding stream alone demands a very specific set of skills, political awareness, knowledge and expertise.

Equally, due to the small scale and limited resources of their organisations, little resource to support management development or training is available. This is in part due to budgetary constraints, but is also a function of the smallness of organisations which cannot afford to release their key staff on anything approaching a regular basis. Even where the organisation is situated close to a conurbation with a further or higher education establishment, it is unlikely that any directly relevant educational opportunities will be available.

Most surprising of all perhaps, is that, in an area renowned for tourism and agriculture, the voluntary sector comprises the single largest type of employment.

In 2000, Exeter College in conjunction with Plymouth University and the Exeter Council for Voluntary Services recognised the needs of the sector and set out to develop a qualification that would be relevant to managers in the sector.

The first stage of this process was to obtain validation for a 'Foundation Degree'. This qualification, new to the UK, is a two year 'sub degree' which deliberately combines the academic with the vocational. It is intended to be sufficiently academically rigorous to enable the successful learner to acquire a full Bachelors Degree after only one more year's study on an Honours programme, while at the same time being sufficiently vocational to represent a real contribution to the learner's current employment or future employability. A Foundation degree differs from a conventional undergraduate programme in a number of ways, most notably in the emphasis that is placed on the development of skills, both those relating directly to a profession, to be acquired in work or on work placement, and those more generic capacities identified as desirable by employers more widely. The qualification is also entirely modularised, less common in the UK perhaps than elsewhere, and can also include accredited elements of professional diplomas or certificates relevant to the area of study.

This choice of qualification was driven by a number of requirements. Firstly, it had to be sufficiently modular and flexible to be attractive to learners with many demands on their time. Secondly, it had to offer something both to those looking for personal or academic development, and to those simply looking for job related training. Thirdly, it had to be structured in a way that would enable those with existing degree, or even masters, level

qualifications to obtain credit for their previous learning while still offering them the specific learning that they desired.
